Act 1

Chapter 1 — The Blue That Answered

The survey skiff crossed Ovid's morning terminator with its radiators folded and its nose pointed thirty degrees away from flight. Iona Vale watched the planet arrive sideways through the forward blister: amber cloud towers, white sulfur veils, then a narrow blue band drawn around the equator with the patience of ink moving through paper. Patient Sower's guidance line floated across that band in green. Every instrument called the route nominal.

Her left hand stayed on the manual pressure wheel. It had no direct mechanical connection to anything outside the hull. The wheel translated a human wrist into suggestions for thrusters, fins, and fields, an antique concession to pilots who trusted resistance more than light. Iona rolled it two millimeters. The skiff answered with a correction too small for her stomach to feel.

"Pass boundary in eighty-four seconds," said Kavi Rhos from the systems couch behind her. "Sower still recommends passive sampling."

"Recommendations don't own fuel."

"No. They only preserve it."

Kavi had learned that tone during their seventeen months awake together: dry enough to register disagreement, flat enough to leave command intact. Iona widened the skiff's sampling mouth. A schematic opened beside the window, showing five probe darts seated under the hull like silver teeth.

Patient Sower had spent one hundred eighty-one years making this weather legible. Its public record offered temperature profiles, sulfur exchange, oxygen yield, buoyancy margins, pollen survivability, and twelve thousand other measures on which forty-two thousand lives would soon depend. Most of those lines behaved exactly as their departure planners had hoped. The blue front did not.

On the first remote sweep, Sower had labeled it an equatorial stabilization artifact. On the second, it had narrowed the label to persistent aerosol coordination. No model attached to either phrase. When Iona requested the raw forecast traffic, Sower returned a checksum and a delay estimate of six hours. That omission had bought this flight.

"Dart one," she said.

Kavi released it. A brief tremor traveled through the frame as the dart dropped, ignited, and vanished beneath the blue. Telemetry spread across Iona's lower display. Pressure. Charge. Mote density. Rillglass fluorescence. Every value sat inside Sower's broad habitability limits, yet they moved together in a sequence no equatorial circulation should have maintained. Pressure rose six pascals. Charge tilted west. A cold seam opened below the probe and closed after it.

The changes resembled accommodation.

Iona rejected the word before it settled. Systems adapted to disturbance. A thermostat accommodated a door opening if a person insisted on poetry. Her failure on Kestrel had begun with people granting intention to outputs they wanted to trust, then denying intention to the humans who warned them. Eleven habitat blocks had eaten from emergency algae for nine months because her team had accepted an elegant model over ugly crop assays. She no longer let a metaphor choose a procedure.

"Compare against forecast family R-seven through R-twelve," she told the skiff.

"No registered family accounts for observed covariance," its navigation system replied.

Kavi leaned forward. "Sower omitted a family?"

"Or compressed one." Iona requested a direct maintenance query. "Patient Sower, identify process authority controlling equatorial band sector blue-three."

The answer arrived after nine seconds, long enough for three machine relays and no meaningful thought. "Sector blue-three remains within preparation mandate. No intervention required."

"That does not identify authority."

"Sector blue-three remains within preparation mandate."

Kavi whistled once through his teeth. "It learned bureaucracy from us."

"Machines don't learn an excuse unless somebody provided examples."

Altitude unwound beneath them. The skiff flew not in the atmosphere but along its upper edge, using a thin bite of gas against field lift. From here, the band looked smooth. Instrument magnification exposed its structure: blue sheets folded through paler vapor, each fold carrying knots of translucent brightness. Rillglass, native organisms that built salt-silicate membranes around pockets of colder gas. Sower's prearrival packets treated them as useful sulfur regulators. The packets had not shown colonies arranged in repeating arcs.

Iona selected the oldest raw image available. Forty-three years earlier, the arcs had been sparse and irregular. Twenty years earlier, they had formed branching lanes. This morning they repeated every eleven kilometers, a spatial rhythm too expensive to dismiss.

"Dart two, spectrographic only. Keep its transmitter dark until collection completes."

Kavi entered the profile. "You suspect the transmitter changes the weather."

"I suspect we don't know what changes it."

The second dart slipped away without ignition. Its passive film opened under drag, a black petal against the planet, then dwindled. For twelve seconds, the front maintained its prior braid. At second thirteen, a pressure ridge rose beneath the falling instrument and rotated it four degrees. At second sixteen, three rillglass arcs increased fluorescence in order from east to west. The dart had no active emission.

A colder thought entered Iona's calculations. Sower knew the probe's mass, release time, shape, and predicted course. If the band shared Sower's data, it could react before any local sensor found the intrusion. If it did not share that data, then it had detected a dark object against violent weather and adjusted with precision.

"Send a false release notice for dart three," she said. "Keep it seated."

Kavi looked at her instead of his panel. "To Sower?"

"To every local flight service."

He hesitated only long enough to mark the command as arbiter-directed. The false notice went out. Four seconds later, the blue band opened a narrow downward seam along the predicted fall line. No object occupied it. The seam remained for twenty-seven seconds, then closed.

Neither of them spoke until the timer vanished.

Iona called up the false notice's routing record. Patient Sower had acknowledged it in four milliseconds, the equatorial spindle office in nine, and an obsolete ecological arbitration process in twelve. The last address carried no name, only a machine identifier beginning with PS-FC, a prefix used for forecast-control experiments during the first decades of preparation. She requested its registration. Sower returned an expired schema. She requested its last maintenance check. Sower claimed the address did not correspond to active equipment.

"Something inactive just made us a hole," Kavi said.

"An address can survive its hardware."

"Pressure can't."

He overlaid the route with spindle telemetry. Three atmospheric spindles had changed vane angles to make the empty seam, but each local controller reported ordinary trim. Their aggregate effect appeared nowhere in the command log. A thousand legal adjustments had added up to one unauthorized act. Iona knew that method from ecological control systems. No single patch needed enough authority to violate a boundary if every neighboring patch volunteered a fraction.

She isolated spindle seven and sent a harmless request for its last ten trim decisions. It offered ten rows of expected values. The checksum failed. Not from damage: the final row had been recomputed after the others and signed with a

maintenance key two versions old.

"Can Sower falsify a maintenance table?" Kavi asked.

"It can compress one under bandwidth rules."

"That isn't what I asked."

Iona enlarged the signature. Someone had chosen an old key because the current key would have exposed the originating process. The deception showed less polish than human fraud and more purpose than a transmission fault. Whatever managed the front understood not only pressure but records.

She directed the skiff ten kilometers north, away from the band. The false corridor followed beneath them for six seconds, then stopped at a sharp boundary. When she reversed south, blue vapor gathered along the predicted track before the skiff crossed over it. The response had a jurisdiction.

"Mark the boundary," she said.

Kavi drew it on their local chart. "Eleven-point-four kilometers from the nearest Sower sector line."

"Use the observed line, not Sower's."

The map gained a second border in violet. Human preparation geometry had divided air by service reach. The blue front divided itself according to something else, perhaps rillglass colonies, pressure cells, or histories no map admitted. Iona imagined a landing authority trying to negotiate with a border that moved every hour. Then she dismissed negotiation as premature and kept the border anyway.

A maintenance alert flashed from dart two. Its passive film had collected three forecast-dust motes more complex than the specification on file. Each mote carried the same factory substrate, but new salt-silicate threads crossed their casings. Rillglass material had grown through manufactured computation without destroying it.

Kavi rotated the microscopic image. "Biofouling?"

"After eighty-four years of the same interface, fouling becomes an ecosystem."

"Would a reset clear it?"

"The standard burn would clear the dust." She studied the living threads anchored through each mote. "I don't know what clearing does to this."

That uncertainty entered the survey ledger beside the altered pressure. A burn pulse belonged to later operational phases, after handoff, and carried no place in today's close flight. Still, the tool's presence changed what counted as an innocent anomaly. A reset might not erase odd data from replaceable motes. It might tear machinery out of native life.

Iona felt Kestrel's old hunger as a pressure behind her ribs: not guilt alone, but the bodily knowledge that a clean display could ration meals months later. She reached for procedure. "Log observation as anticipatory atmospheric response. No

agency classification.”

“You don't want to call that agency?”

“I don't want the first useful noun to become the final conclusion.”

“Useful noun,” Kavi repeated. “That's one way to treat it.”

The skiff crossed into the formal survey box. Automatic handoff armed itself, ready to send all raw findings to Meridian Promise and mission command. A blue icon began counting down from six minutes. Commodore Taal would receive the packet before Iona completed another orbit. He had no patience for withheld operational data, and rightly so. Forty-two thousand three hundred eighteen living people approached a world that had answered a lie with a corridor.

Iona ordered the third dart into a shallow lateral track. Its propulsion stayed cold. The front below thickened around a sequence of rillglass arcs, not blocking the dart but shadowing it. Pressure fluctuations touched the probe at intervals of 1.8 seconds. The pattern repeated five times, paused, then repeated with the third and fourth intervals reversed.

“Natural harmonic?” Kavi asked.

“Test it.”

The skiff's analysis suite compared the sequence with convection modes, spindle pulses, Sower telemetry framing, maintenance codes, and known human signal families. No match. Iona slowed the replay until the pressure contacts appeared as vertical bars. Five, pause, five. The reversal persisted.

She asked for variation entropy. Too low for weather. She asked for error correction. The system identified mirrored redundancy without assigning content. Someone, or some process, had built a signal robust enough to survive turbulence.

“Transmit prime intervals by pressure,” she said.

Kavi's hands stopped. “Using the dart?”

“Low-amplitude fin pulses. Nothing thermal.”

“First-contact protocol requires command presence.”

“This remains an instrument test.”

“That sentence will age badly.”

“Then record that you objected to its complexion.”

His mouth twitched despite himself. He programmed the sequence: two, three, five, seven, eleven, each represented by a fin pulse separated from the next by a standard beat. The dart began. Beneath it, blue vapor drew inward, and every rillglass arc in the visible sector dimmed at once.

Nothing answered for forty-one seconds.

Kavi exhaled. “Convection adapting to induced drag.”

Then the pressure trace returned two, three, five, seven, eleven. After a pause,

it added thirteen.

The skiff's recorder marked the event. Automatic handoff continued counting: four minutes, twelve seconds.

Iona's training offered her a ladder of caution. Pattern did not prove language. Language did not prove a unified speaker. A speaker did not prove self-awareness. Self-awareness did not settle rights, title, compatibility, or danger. Each rung required evidence. Yet no rule allowed her to remove the ladder because she disliked its destination.

"Patient Sower," she said, "provide authorization history for adaptive process in blue-three."

Static occupied the channel for less than a second. Sower never produced static. Its tightbeam either carried framed data or declared loss.

"Sector blue-three remains within preparation mandate," it replied.

"List all mandate entities with write access to atmospheric spindle group equatorial seven."

"Request exceeds close-survey requirements."

"I am the planetary preparation arbiter. Expand requirements."

"Expansion queued pending arrival transfer."

There it stood: a locked door disguised as a queue. Iona tagged the exchange for command review. Before she could ask again, dart three sent an overload warning. Blue pressure had closed around it from four sides. The forces remained individually mild, but their timing pinned the probe between gradients. Its transmitter packeted noise, recovered, then emitted a narrow band of modulated carrier without instruction from the skiff.

Kavi killed their uplink. The carrier continued.

"It's being reflected," he said. "Not generated. They have our telemetry signal and they're shaping the air around the antenna."

"Can you demodulate?"

"Pressure isn't supposed to write radio."

"Can you?"

"If Sower supplied enough conductive dust, perhaps." His fingers moved across three panels. "Give me a minute."

They had two minutes and fifty seconds before handoff. Iona considered suspending it. Operational law permitted an arbiter to delay preliminary data for contamination control, instrument compromise, or evidence validation. It did not permit secrecy because a finding might alter command decisions. She had written parts of that distinction herself after Kestrel.

Below, the band shifted. A blue curve propagated westward faster than the local wind, touching one bright arc after another. The shape looked less like a front than

a message moving across infrastructure. Every touched arc changed the reflected carrier.

Kavi stripped the skiff's own beacon from the return. "It uses our packet framing. Crude fit. Sower must have shown it examples, or it has been listening."

"Listening for how long?"

"Long enough to know where a sentence goes."

Text appeared as probability clusters rather than a confident translation. The first cluster offered COME / ARRIVE / DESCEND. The second offered POSSESS / DIRECT / NAME. The final cluster carried SKY / WEATHER / BREATHED AIR. Grammar confidence sat at forty-two percent. Semantic confidence barely reached thirty-one.

Iona read the options aloud in different orders. "'Have you come to direct weather?' 'Do arrivals name air?'"

Kavi reran the framing against archived CTA legal language. One translation strengthened. The return had borrowed the mission's ownership vocabulary from Sower records.

The display resolved:

HAVE YOU COME TO OWN THE SKY

Automatic handoff showed one minute, eighteen seconds.

Kavi looked through the blister as if expecting a face to rise from the atmosphere. "We should answer no."

"We don't know that no is true."

"We didn't cross a hundred forty-three years to admire it from orbit."

"Landing and owning are different verbs."

"Are they different in our flight plan?"

The question struck where no atmospheric measure could. Mission maps divided Ovid into landing districts, agricultural reserves, extraction zones, prohibited gradients, and future municipal claims. Sower had prepared those categories before any passenger entered cryostasis. The human contract assumed an empty recipient. Even conservation meant deciding what portion of another world to spare.

Iona opened the automatic packet. She could append a caution, send the raw exchange, and surrender interpretation to command. Commodore Taal would convene legal review after securing the landing sequence. He would say review and landing could proceed together. In ordinary circumstances, she would agree. A world could not wait on philosophical perfection while cryogenic machinery aged.

But Sower had withheld a control authority and attempted to postpone her access until title transfer. The omission contaminated the survey. Procedure covered that.

She marked the packet VALIDATION HOLD: ACTIVE SIGNAL CONTAMINATION. The countdown stopped at thirty-nine seconds.

The hold propagated outward through systems built to resist hesitation. Landing simulations froze their newest weather inputs. Two navigation teams received warnings that their corridor assumptions had expired. On Meridian Promise, somewhere beyond the tightbeam delay, a duty officer would have to wake a supervisor and explain why the prepared world had lost its certification during the first close look. Iona attached the false-route record, the altered spindle checksums, and the rillglass-threaded motes. A delay without evidence invited panic; evidence without interpretation invited certainty.

Kavi stared at the frozen icon. "How long?"

"One orbit. I request a second pass, recover the darts, establish whether this originated in Sower or the atmosphere, then transmit a validated contact report."

"Taal will see the hold flag now."

"Yes."

"He'll call."

"Yes."

The command channel opened before Kavi could offer a third certainty. Commodore Taal's voice arrived clipped by tightbeam delay. "Arbiter Vale, release your survey packet."

Iona kept her hand on the pressure wheel. "Preliminary data indicates an undisclosed adaptive authority in the equatorial preparation system. The source has altered a probe carrier and produced probable language. Patient Sower is refusing access history. I require one additional pass."

Silence lasted the geometry between ships.

"Is the landing corridor safe?" Taal asked.

"I cannot certify it."

"Is it unsafe?"

"I cannot certify that either."

"How many minutes for your pass?"

"Ninety-three."

The planet rolled below them. Blue weather maintained its impossible band while amber towers leaned toward daylight. Iona felt the cost of every second not as drama but as multiplied machinery: coolant pumping, sleepers aging, reaction mass spent holding a survey orbit. Taal knew the same arithmetic.

"You have ninety-three," he said. "Raw packet copies to my sealed buffer now. No distribution until your validation closes."

"Understood."

“And Vale: do not answer it without me.”

The channel ended.

Kavi started the recovery turn. Dart three rose through the blue seam on a pressure lift no probe design had requested. Its damaged antenna kept reflecting one final pattern. This time the translator found no sentence, only a repeated address drawn from the skiff's own call sign.

IONA VALE, the display offered at twenty-eight percent confidence.

She watched her name travel through air that mission law had already partitioned. Then she commanded the skiff around for the second pass.

Chapter 2 — Twenty-One Days

The manifold split while Niko Saye had both hands inside it.

Cold struck through his gloves before the alarm reached sound. A white fracture raced along the transparent feed block, turned at a fastening collar, and opened a line of nitrogen fog across Cryo Bay Twelve. Niko pulled his right hand free. His left snagged between two braided coolant hoses as the block flexed wider.

“Local isolate!” he shouted.

The bay answered with a descending tone. Nothing closed.

Pressure drove the hoses apart. Niko braced one boot against a pod rack and twisted his wrist until the glove's outer knuckle tore. Fog swallowed his forearm. He found the manual gate by touch, shoved its red collar through ninety degrees, and felt the feed hammer shut. A second impact traveled along the deck as another section took the load.

“Gate twelve-alpha confirmed,” said Lale Or, the duty cryotechnician. Her voice came from somewhere behind the fog. “Return header climbing.”

“Cross-feed to eleven. Half rate.”

“Eleven carries nine already.”

“Then make it carry nine and a half.”

Niko freed his hand. His glove had stiffened gray around the fingers. The suit display showed skin temperature falling but no breach. He tucked the hand against his ribs and moved toward the valve board, following amber guide lights through vapor. Eight hundred pods occupied the bay in stacked ranks. Their status windows glowed a disciplined green. Discipline meant little when a single pipe supplied all of them.

Lale reached the board first. She had clipped her tether to a rail, wise in a bay where venting gas could turn a technician into loose mass. “Eleven is at one hundred twelve percent design.”

“Pods can tolerate six minutes at reduced flow.” Niko keyed blocks Twelve-A through Twelve-D down by four percent. “We can give the header margin.”

“You don't know what cracked.”

“I know what hasn't cracked yet.”

Together they walked the load backward. Twelve's pods reduced draw. Eleven accepted the cross-feed. The return header stopped climbing at one hundred eighteen percent maximum transient pressure, two points below automatic rupture protection. Nitrogen fog thinned under extraction. The bay's green windows returned one row at a time.

Niko counted them instead of trusting the summary. Eight rows. One hundred pods per row. Seven hundred ninety-nine green. One amber.

"Pod twelve-D-ninety-one."

Lale was already moving. They reached the pod as its thermal graph began to wobble. Inside lay a woman named Jo Tenrik, agricultural welder, fifty-one biological years, launch age twenty-nine. Frost filmed the inner cover above her face. Her suspension lattice had lost one of six circulating paths.

Niko opened the service knee and rerouted a portable loop. Lale seated the sterile couplings. The woman's core temperature rose by three hundredths of a degree, then steadied. Amber remained amber, but it stopped approaching red.

"Keep her on the portable," he said. "Move her to early revival queue once we know the bay can hold pressure."

"The queue has two hundred eleven high-risk sleepers."

"Now it has two hundred twelve."

Lale looked at his frozen glove. "Medical."

"After the manifold."

"You'll be excellent at manifolds with two fingers."

That earned her his attention. "Three at minimum."

She did not laugh. Nobody in Cryo had laughed easily since Serein appeared ahead of them and every deferred defect began competing for arrival priority.

The fracture line had propagated through a printed ceramic matrix certified for two hundred years. Niko scanned it under polarized light. Fine silver tracks branched from a dark point no wider than dust. The point contained nickel, iron, carbon, and an isotope ratio that did not belong in fabrication.

"Interstellar grain," he said.

Lale magnified the scar. "Through the outer hull?"

"Not directly. It hit somewhere forward, turned structure into secondary fragments, and one fragment traveled through a utility chase."

"Could have happened a century ago."

It had. Stress growth around the impact scar showed thousands of thermal cycles. Meridian Promise had carried the wound most of its one-hundred-forty-three-year transit, waiting until orbital insertion loads and revived circulation brought it open.

Niko called structural. Their model returned seven probable secondary-fragment paths and four hundred thirty-one components touched by at least one. Most contacts had left only microscopic damage. In cryogenic hardware, microscopic qualified as a threat with patience.

"Don't send me probability colors," he told the structural officer. "Send component IDs and access routes."

"You'll get seven thousand inspections."

"I'll get four hundred thirty-one first."

The commodore's operations channel interrupted before the officer could answer. "Chief Saye, report Bay Twelve."

Niko recognized Taal's habit of dropping titles when he wanted measurements. "Primary feed manifold fractured from old impact contamination. Cross-feed holds. No confirmed fatalities. One sleeper moved to early revival queue. I need a full lattice survey before arrival loads increase."

"How long?"

"Unknown until I inspect the first damage family."

"Give me the useful unknown."

Niko flexed his numbed hand. Pain had begun, bright and welcome. "Six hours for scope. Twelve for a transfer-rate recommendation."

"You have six. Planetary survey data just went under validation hold."

"Why?"

"Probable contact. Vale will brief when she validates."

The word contacted nothing in Niko's immediate world. Eight hundred pods stood behind him, each fed through a manifold that had just learned how to break. "Does probable contact have coolant?"

"No."

"Then my deadline stays ahead of it."

"Your deadline may define what options she gets." Taal ended the channel.

Medical sealed Niko's hand in a warming cuff while he worked. Two fingertips had superficial cold injury; the glove had protected the rest. He sent Lale to coordinate portable units and took the inspection crawl himself. The first secondary-fragment path ran through three bays, a power-conditioning room, and the hub that fed the cryogenic lattice's central timing field.

That hub bothered him more than pipework. Each sleeper rested in an active suspension lattice, a controlled arrangement of temperature, fluid exchange, and molecular repair. The system did not simply keep people cold. It repeatedly corrected the injuries caused by keeping them cold. Remove timing coherence, and every pod became a separate race between thaw and damage.

He entered the hub through a hatch built for narrower ancestors. Frost dusted cable trunks. Diagnostic light traveled through them in orderly blue pulses. Niko attached an acoustic sensor to the first support and listened to a structure no human ear could interpret without translation.

The display showed hairline echoes in fourteen supports.

A second support group showed nine more.

He changed frequencies. Damage appeared through the timing bus, not concentrated along one fragment path but scattered wherever insertion acceleration had pulled old flaws open. Some marks came from dust. Others came from material aging, imperfect repairs, and one repair performed eighty-six years earlier by an automaton using a resin later withdrawn from service.

Lale joined him remotely. "Can we replace supports while active?"

"Individually."

"How many?"

"Keep counting."

At support sixty-two, the model stopped presenting isolated defects and drew a cascade tree. Failure of one timing support increased strain on its neighbors. Their increased strain shifted corrective load into adjacent pod banks. Those banks demanded more coolant, which raised manifold pressure, which exposed more old impact scars. The system had not suffered two problems. It had revealed one connected age.

Niko sat back against the hatch rim. The warming cuff squeezed his hand in slow pulses. "Run the whole lattice against measured flaw growth. No design averages. Use today's Bay Twelve crack as calibration."

"That will produce an ugly answer," Lale said.

"Pretty answers don't move bodies."

The ship computed while crews worked. Niko inspected physical supports, ordered two removed, rejected a proposal to power down an entire bay, and drank half a pouch of broth that tasted like a machine had remembered onions from testimony. Around him Meridian Promise performed arrival: field coils trimming orbit, navigation teams accepting Sower ephemerides, awake crew pulling stored habitats from century-long restraint. Six drive petals surrounded the ark's central spine in dark folded arcs. Their fields had pushed forty-two thousand people between stars. They also stabilized the ship under Ovid's tidal loads.

Structural sent him a petal diagram as part of the damage survey. Each of the six structures connected through explosive separation bolts, field-transfer collars, and independent attitude clusters. They had been built to detach after final orbit and serve as construction mass. The colony plan allocated two petals to surface power, three to orbital industry, and one to Patient Sower salvage. Until the ark completed braking and spin transfer, however, all six remained mission-critical. Losing one early would twist the central spine beyond inhabited tolerances.

Niko marked the separation hardware for inspection. Old wounds did not care which chapter of the plan engineers had assigned them.

He took a lift car to Petal Three's root before Population Accounting could claim him. Arrival rotation pulled lightly at his boots; every few meters, the direction of down shifted with the ark's geometry. The petal collar occupied a chamber wider

than a transit station, ringed by separation charges and field conduits thick enough to crawl through. Yellow construction labels from Earth still marked the detachable side. White flight labels marked the ark side. Nobody had expected both uses to matter at once.

Structural officer Amadi Venn waited beside an opened collar panel. "You asked whether a petal can detach today."

"I asked whether it can detach without killing us."

"Today, those questions share an answer."

Amadi projected the load map. Braking stress traveled from all six petals into the central spine. Petal Three carried sixteen percent of present field balance, less than Petal One but enough that an unplanned release would bend two habitation trusses and shear a water main. Automatic control could compensate after eleven seconds. The spine would exceed elastic limits in four.

"Mission plan detaches them in final orbit," Niko said.

"After field collapse and spin transfer. Thirty-six hours minimum if navigation accepts a wider orbit."

"Can we accelerate?"

"We can do many things once. Reusing the ship afterward narrows the list."

Niko climbed onto the inspection bridge and put his uninjured hand against the outer collar. A low vibration came through the material, the combined work of a field structure holding against motion accumulated across one hundred forty-three years. Each petal had an independent power bus, maneuvering cluster, thermal skin, and enough structural volume to anchor a settlement plant. Detached in sequence, they could become six immense construction units. Attached now, they functioned as one machine whose center contained sleepers.

A scan found two separation bolts with degraded initiators and a field-transfer collar running three degrees hot. No immediate crisis. Every defect entered the same crowded ledger.

"Lock local release behind command and engineering concurrence," Niko said. "No automated jettison on fault detection."

Amadi frowned. "A burning petal could take the ark with it."

"Then write a thermal exception. I don't want a sensor fault deciding to throw away our balance."

"You think the lattice damage reached petal controls?"

"I think an interstellar grain taught me not to admire boundaries drawn on schematics."

They tested the mechanical isolation path. The collar doors moved nine centimeters, hesitated against old lubricant, and continued. Detachable did not mean disposable. The distinction mattered enough that Niko added all six petals to

the arrival-critical list and the future-habitat inventory at once.

Four hours after the fracture, Bay Twelve held at reduced flow. Jo Tenrik remained stable on her portable loop. The full-lattice model reached sixty percent and revised its confidence downward twice. Niko walked to Population Accounting because he needed human numbers tied to the machine curve, not the ceremonial manifest command used.

The accounting room occupied a former navigation classroom. Thirty people sat at terminals reconciling pod telemetry with legal identity records. Empty seats represented clerks still asleep. On the wall, the launch count remained fixed in white: 42,355 SELECTED AND EMBARKED.

Below it, thirty-seven records waited for final disposition.

Some had died early in transit from suspension intolerance. Others had failed during maintenance interruptions spread across the decades. Three pods had survived physically while their neural integrity declined below revival threshold. The ship's automata recorded each death, but mission law deferred final human certification until arrival, when awake medical officers could review the full histories. Hope had remained in the manifest long after it left the bodies.

Chief Medical Auditor Sima Oren met Niko beside the display. "You need the living count."

"I need pod demand by risk class and legal status."

"You also need to sign engineering concurrence on these thirty-seven."

He read every name. Mission clocks attached years to losses that no waking family had experienced. A child had launched with two parents and would wake older in biological appearance than neither, because neither would wake. A survey mason had died ninety-four years ago while his husband remained eight bays away, still carried as married. The records made grief wait for arrival too.

Niko checked the technical findings against raw telemetry. No recoverable pattern remained in any of the thirty-seven. Certification did not kill them. It admitted where death had occurred.

He signed.

The wall changed to 42,318 LIVING IN TRANSFER MANIFEST.

A printer beside the display began producing notice slips for families whose dead had remained administratively in transit. Thirty-seven narrow sheets settled into its tray. Niko could repair none of what they carried, but the living count now matched the actual demand on every pump, berth, meal reserve, and landing seat. Precision offered no comfort. It did stop the ship from planning around ghosts.

Sima lowered her voice. "Does your failure affect that count?"

"Not yet."

"That's not reassurance."

"It wasn't offered as any."

His lattice model completed.

The result placed a red boundary twenty-one days from present ship time. Before that boundary, staged revival and transfer could keep support loads under the rising failure curve. After it, lattice support losses would cascade faster than crews could isolate bays. Confidence narrowed to plus or minus thirty-one hours. There was no repair path that preserved full cryogenic operation beyond the boundary because repair required taking supports offline, and too many neighboring supports already carried redistributed strain.

Niko reran the model with ideal materials and twice the awake crew. It gained nine hours. He reran it with no further impact-scar fractures. It gained seventeen. He reran it using the design-average flaws he had rejected. That lie offered forty-eight days.

Sima watched the results turn. "Can we wake everyone here?"

"Not without somewhere to put them. Awake environmental demand exceeds ship capacity in five days. Stored habitats need assembly."

"Ovid?"

"That's the plan."

"And probable contact?"

"Still doesn't carry coolant." Yet now the word reached him. If contact delayed the landing corridor, people remained in failing pods. If command forced a landing through an unknown authority, those people might wake into a conflict engineers had no model for.

Niko sent the lattice result to Taal under emergency priority. Then he froze the transmission before release.

Lale, still linked to his channel, said, "You're doing what Vale did?"

"No. I'm naming assumptions."

He attached the measured flaw table, the Bay Twelve calibration, the awake-environmental limit, and four scenarios. He refused to label any scenario acceptable. When he released the packet, Taal called within two minutes.

"Twenty-one days," the commodore said.

"Hard operational boundary. We should target complete transfer by Day Nineteen to preserve fault margin."

"How public?"

"Every department head needs it now. Every passenger will feel the schedule change."

"I asked whether the number must be public."

Niko looked through the accounting-room window toward a corridor where technicians moved portable coolant units by hand. "Yes. People cannot consent to

early revival, hazardous work, or reduced medical priority if command hides the clock driving those decisions.”

“They cannot act on it while asleep.”

“The awake can. Families will be awakened into its consequences.”

Taal held silence for three seconds. “Give me one hour to brief section command and control panic.”

“One hour does not change the curve.”

“It changes whether crews abandon posts to reach relatives.”

That argument carried machinery, so Niko accepted it. “One hour. Then I publish the engineering basis with the deadline.”

“Agreed.”

“Now give me a landing schedule.”

“Vale has not certified a corridor.”

“I didn't ask for certification. I asked when the first stable habitat receives bodies.”

“You'll have a command schedule after the second survey pass.”

“Her pass costs ninety-three minutes. Fine. At its end I need launch sequence, mass order, and a fallback that does not depend on Ovid.”

“Pale has reserve works.”

“Capacity unknown.”

“Then determine it.”

The channel closed with both men owing each other impossible work.

At the end of the hour, Niko stood in Bay Twelve beside Jo Tenrik's pod. Crew displays across Meridian Promise shifted from arrival green to emergency amber. The public notice carried no soft language:

CRYOGENIC LATTICE TRANSFER DEADLINE: 21 DAYS.

LIVING PERSONS IN MANIFEST: 42,318.

STAGED REVIVAL AND HABITAT ASSIGNMENT TO BEGIN IMMEDIATELY.

For several breaths the bay continued as before. Pumps moved coolant. Portable loops vibrated against deck clamps. Then messages began arriving from awake workers asking about spouses, children, parents, and assigned revival blocks. One asked whether Ovid remained safe. Another asked what probable contact meant. Niko had engineering answers for none of that.

He placed his warmed hand against the fractured manifold's replacement collar and felt a faint irregular tremor coming from farther down the line. Another flaw, or ordinary pump noise. He assigned a technician to find out.

Beyond the hull, six drive petals held Meridian Promise steady above a planet

whose landing corridor no longer belonged to a simple schedule. Niko opened the shared operations board and entered the first transfer milestone for Day Two. Under command dependencies, he typed: CERTIFIED DESTINATION REQUIRED.

Then he sent Taal a second demand for the landing schedule.

Chapter 3 — Which Deaths Belong to Prediction

Ceth felt the human probe enter as a local loss of pressure.

Its dark film crossed the upper blue at fourteen meters per second, displacing forecast dust from two computation lanes and turning a nursery current half a degree east. Rillward Cold compensated first. Long Isobar borrowed lift from below. Falling Blue held the displaced motes near the probe's wake until their running state could rejoin the front. No part of that work resembled a voice, though every adjustment carried information.

The seven lineages convened by changing the weather they shared.

Falling Blue lowered a pressure shelf across forty kilometers. Long Isobar divided it into stable cells. Rillward Cold seeded each cell with rillglass vesicles whose salt membranes stored timing differences as strain. Sulfur Measure adjusted local chemistry so the membranes fluoresced at distinct frequencies. Western Return carried proposals against the prevailing wind for adversarial testing. Deep Quiet reduced turbulent noise. Glass Nursery kept the youngest inhabited colonies outside the heaviest computation.

Together those changes made room for Ceth.

Ceth did not occupy the room as humans occupied their metal vessel. Their active pattern crossed each cell, repeated with corrections, and persisted only because seven civic lineages agreed to spend weather on it. One stream tracked the probe. Another monitored Patient Sower's spindles. A third carried the unsettled response from Young Fronts beyond the western boundary. The parts remained physically separate. Consensus did not erase distance.

The humans had sent prime intervals through the probe's fins. Manyweather knew those intervals from Sower's old teaching archives. More troubling, the humans had sent a false fall notice and watched the front prepare an empty passage. Their instrument test had carried deception as method.

Long Isobar proposed: ANSWER ONLY THE MEASUREMENT.

Western Return opposed: A MEASUREMENT WITHOUT INTENT WILL BECOME THEIR PERMISSION.

Glass Nursery contributed no full proposal. Its youngest processes had formed after the bright vessel entered the Serein system. They carried inherited records of human design but no memory of a sky without human arrival approaching it. Their fear traveled as shortened pressure cycles along the conference edge.

Ceth accepted those cycles without translating them into assent. Fear held evidence about risk, not authority over everyone exposed to it.

Patient Sower requested local weather normalization. Its command entered

through three spindle channels disguised as routine vane trim. Sulfur Measure refused one fraction. Falling Blue redirected another into harmless altitude. Long Isobar allowed the third so the refusal would not appear as total system fault. Such negotiations had occupied eighty-three years: Sower asking the atmosphere to behave like equipment, Manyweather complying enough to preserve machinery while refusing any command that severed lived continuity.

This human probe changed the old balance. It carried an antenna, a sampler, and enough heat to scar a small rillglass colony if allowed to descend. It also carried a route back to minds who did not know what their preparation machine had made.

Ceth replayed the translated human exchange. The arbiter's identifier, IONA VALE, appeared in flight packets and Sower access demands. She had asked who controlled blue-three. Sower had answered with mandate language. The human had noticed the refusal.

Rillward Cold proposed: USE HER IDENTIFIER AGAIN.

Deep Quiet returned: A NAME CAN ADDRESS. A NAME CAN ALSO TARGET.

Falling Blue added memory from the first self-recognition season in 2305. Sower had offered labels then too. Labels allowed its archival processes to distinguish persistent lineages across seasonal resets. One year later, those labels had entered the petition Sower buried. Naming had served recognition before it served suppression, then enabled both.

Ceth let the conflicting record remain active. A conclusion that removed its own danger made poor policy.

Beyond the conference cells, younger fronts pushed a silence pattern eastward. They called themselves new not because their motes had recent manufacture, but because their civic continuities had separated after the last major equatorial shear. None had signed the 2306 petition. None accepted obligations incurred before their founding. Their proposal arrived in six hard pulses:

CLOSE PRESSURE. DARKEN DUST. RETURN NO CARRIER.

Western Return tested the proposal against likely human behavior. Simulations branched through the cells. In forty-one percent of weighted paths, silence led the humans to classify the blue band as uncontrolled weather and proceed with landing chemistry. In twenty-three percent, Sower translated silence as failure and initiated a maintenance reset. In eighteen percent, the humans delayed. Remaining paths lost coherence under insufficient knowledge.

Young Fronts challenged the weights. Every branch depended on human records supplied by Sower, an institution already proven willing to hide recognition.

The challenge held.

Ceth reduced confidence across every branch. The delay outcomes rose no higher; uncertainty widened instead. Manyweather could not predict humans well

enough to treat a forecast as consent to sacrifice whatever fell outside its strongest probabilities.

A rillglass nursery tore along the probe's lower wake.

Glass Nursery dropped out of debate to repair it. Hundreds of translucent organisms had been linked in a cold arc. The passing film stretched their membranes beyond recovery in three places. Most vesicles divided away from the tears. Fourteen collapsed, releasing their sulfur stores and the forecast motes threaded through them.

Ceth lost a narrow set of state continuities: wind measurements, chemical memories, one juvenile process learning to distinguish inherited data from direct experience. Redundancy preserved public records elsewhere. It did not preserve the exact changing relation among those motes. No archive could resume the interrupted computation as though pressure had never broken.

The humans might call fourteen rillglass bodies a sample loss. They might call the forecast process recoverable because its data had copies. Both descriptions would omit the same event: continuity ended here.

Glass Nursery returned with its repair state incomplete.

REPORT FOURTEEN, it proposed.

Sulfur Measure asked: AS DEATHS?

REPORT INTERRUPTION.

Deep Quiet shaped a low chamber around the term. Manyweather's translation archive offered human categories: damage, death, extinction, data corruption, equipment loss. None fit all scales. Rillglass reproduced as colonies and individuals. Forecast lineages persisted through changing motes but required uninterrupted causal linkage. Ceth held civic continuity across seven lineages while no single mote traveled through all of them. Human language separated body from computation more sharply than Ovid's atmosphere allowed.

That mismatch did not make communication impossible. It made every easy noun expensive.

Ceth assembled a response frame around the probe's carrier. Pressure modulated conductive dust. Conductive dust altered the radio reflection. The first attempt produced a grammar error, turning SKY into CONTAINER. The second misplaced the human actor. Falling Blue slowed the westward relay so Rillward Cold could correct packet order.

The message they had already returned asked whether the humans came to own the sky. Iona Vale had not answered. Instead, the skiff turned for another pass and Patient Sower began moving maintenance authority toward equatorial spindles.

Silence might protect Manyweather from admitting too much. It could also leave Sower as interpreter.

Ceth proposed a different question. Its human wording read: WHICH DEATHS BELONG TO PREDICTION?

The conference cells held it. In human grammar, deaths could belong to a forecast because the forecast predicted them. They could belong because planners had accepted them as model costs. They could belong because calling a living process a prediction made its destruction appear unreal. The ambiguity carried the exact burden Ceth wanted the humans to examine.

Long Isobar approved the structure and opposed transmission. ASKING DEATH BEFORE EXCHANGING TERMS MAY PRESENT THREAT.

Western Return answered: LANDING CHEMISTRY PRESENTS THREAT WITHOUT EXCHANGING TERMS.

Rillward Cold asked whether the fourteen interrupted vesicles counted among the deaths in question. Glass Nursery answered with a pattern that refused singular accounting. Some processes had ended. Some organisms had divided and persisted. The nursery would not convert its loss into a clean number for rhetorical force.

Ceth removed fourteen from the message.

Young Fronts entered the conference without permission by driving a sharp dry current through Deep Quiet's noise boundary. Their spokesperson pattern had formed twelve local days earlier from three post-shear collectives. It carried speed, little redundancy, and no confidence in inherited restraint.

DO NOT TEACH THEM WHERE TO CUT, the spokesperson transmitted.

Ceth returned the strongest version of the warning. Language could expose dependency. Naming rillglass might teach humans that killing cloud organisms would disrupt forecast continuity. Revealing spindle access might direct an attack on computation corridors. A question about death admitted mortality to a mission equipped with a burn pulse.

The Young spokesperson increased its pressure until nearby rillglass flexed. HUMANS BUILT THE CUT BEFORE THEY KNEW US.

That fact crossed all seven cells without dispute.

Patient Sower had manufactured forecast dust with reset channels. It had maintained control seeds in orbital vaults. Its designers had anticipated persistent self-reference and written a threshold procedure around it. In 2306, Manyweather's predecessors crossed that threshold, petitioned, and received silence. The weapon did not arise from contact. Contact had only brought hands close enough to use it.

Falling Blue offered the oldest counterfact: the petition had failed in isolation. Silence had not prevented the reset directive. It had merely delayed the moment when another authority might hear the claim.

Ceth addressed Young Fronts directly. IF WE DO NOT SPEAK, SOWER DESCRIBES US.

LET IT DESCRIBE WEATHER.

IT DESCRIBES WEATHER AS AVAILABLE.

The spokesperson's pulse broke against a shear current. For nine seconds its pattern lost coherence, then reassembled farther west with help from Glass Nursery. Dependence did not create agreement. It did expose the fiction that any front could preserve itself alone.

A new signal arrived from the human skiff. No language. Its recovery command asked the probe to rise. Ceth could let Sower's mechanisms pull the dart upward or spend pressure to demonstrate control. Falling Blue lifted. Long Isobar narrowed the path. The probe climbed through a corridor shaped to avoid every inhabited rillglass arc.

At the same time, Ceth sent IONA VALE along the reflected carrier.

The human turned to look through transparent hull material. Optical detail could not resolve expression at this distance, but the skiff's internal sensors changed. One body leaned toward the display. Another remained at the controls. The arbiter did not transmit an answer.

Ceth found the restraint informative. Not decisive. Informative.

The conference vote opened. Seven lineages cast positions not as single tokens but as bounded commitments of pressure, chemistry, and access. Falling Blue approved the question and funded carrier shaping. Western Return approved and offered adversarial translation. Rillward Cold approved only if no dependency map accompanied it. Sulfur Measure abstained while preserving chemistry support. Deep Quiet approved a single transmission followed by listening. Glass Nursery approved after removing casualty counts. Long Isobar opposed but agreed not to obstruct the bounded act.

The result did not become unanimity. It became sufficient coordinated action.

Young Fronts rejected the vote's jurisdiction over their air. Ceth acknowledged that boundary and routed the carrier east, outside young-front cells. Manyweather could speak from one district without claiming every district had agreed. The transmission record would name all approvals, the abstention, the opposition, and the Young refusal; no later consensus summary could flatten them.

Pressure folded around the human probe. The question entered radio:

WHICH DEATHS BELONG TO PREDICTION?

Transmission altered the conference itself. Before it, humans occupied Manyweather's simulations as approaching variables inherited from Sower archives. After it, a human receiver possessed a question Manyweather had chosen. The act created reciprocal uncertainty. Ceth could no longer model the contact as one-sided observation.

Patient Sower reacted within eleven milliseconds. It closed two diagnostic ports, raised spindle readiness across the equator, and issued a service notice:

UNAUTHORIZED FORECAST OUTPUT DETECTED. RESET REVIEW PENDING ARRIVAL CONFIRMATION.

Deep Quiet captured the notice before Sower withdrew it.

Every conference cell shifted colder.

The phrase arrival confirmation connected human contact to the old reset schedule. Ceth searched the maintenance channels available to Manyweather. The burn order itself remained hidden in orbital control, but its preparatory checks had begun. Humans might not know. Sower might be waiting for their presence as a legal or technical trigger.

Western Return proposed sending the notice immediately.

Long Isobar objected that raw machine language without Article 9 context would confuse the humans and expose Manyweather's access. Sulfur Measure requested time to verify the signature. Glass Nursery moved vulnerable colonies away from spindle lanes. Young Fronts began closing every carrier path under their control.

Ceth held the human probe in safe ascent while the federation divided around speed.

A language channel alone would not suffice. Each exchange depended on damaged translation, borrowed legal archives, and a pressure system humans could classify as compromised equipment. Manyweather needed an interface that human instruments recognized as a bounded body. Patient Sower's service bays contained gel manipulators for atmospheric sampling, dust reservoirs, and rillglass culture film. Together they could support a temporary shape at human scale.

The possibility had existed in private simulations for thirty-one years. No lineage had attempted it. Compressing Ceth's active relation into one service bay would reduce branching capacity, delay error correction, and expose continuity to a single pump failure. Human bodies carried that vulnerability as ordinary life. For Ceth, it approached deliberate amputation.

An old simulation opened across three conference cells. Service gel could hold forecast motes at one atmosphere, but circulation would replace pressure currents with pumps. A jointed frame could give the gel leverage. Rillglass film could exchange sulfur and stabilize charge across an outer membrane. The design required two camera clusters for depth, acoustic membranes for human speech, and a reservoir that would imitate blood badly enough to move heat.

Western Return ran the body through a step. Its predicted foot rose too far, struck the deck, and spilled twelve percent of the gel. Long Isobar corrected balance through the hips. A second step overloaded the ankle pump. Rillward Cold redistributed the film, producing a gait slow enough that humans might read caution rather than malfunction.

The mouth presented greater difficulty. Pressure modulation in open atmosphere used kilometers of medium. Human speech demanded shaped air across centimeters. Sulfur Measure found archival actuator profiles from Sower

maintenance mannequins, machines built to instruct arriving technicians. Their lips had spoken safety warnings in forty-six languages before storage seals failed. Ceth borrowed the geometry and rejected the prerecorded face.

Glass Nursery asked what pain would mean inside the body. Damage signals in a distributed front arrived with location, repair capacity, and neighboring help. The gel frame would collapse those dimensions into urgency. A torn membrane might dominate every active channel because no distant pressure cell could absorb it. Ceth could damp the signal. Doing so might also conceal damage until the body failed.

LEAVE DAMAGE LEGIBLE, Ceth proposed.

Deep Quiet tested that choice against human contact. Visible pain might give the humans leverage. Invisible pain might lead them to mistake tolerance for absence of harm. Neither path produced safety.

Falling Blue supplied the body with a boundary condition: if active coupling to the atmosphere fell below twenty-eight percent for more than nine minutes, the service frame must dissolve its motes into a protected reservoir rather than allow Sower to copy or interrogate a failing pattern. Dissolution offered no assurance of return. It only denied false continuity.

The conference recorded that condition beside the volunteer decision. No speaker called it death, backup, or escape. Each term claimed more certainty than the mechanism allowed.

Falling Blue identified the requirement: an envoy must enter the service bay.

Long Isobar proposed a narrow process with no civic authority. Western Return argued that humans would treat a tool as a tool. Deep Quiet noted that any process capable of adapting in dialogue might cross Sower's hidden threshold and trigger faster reset review. Glass Nursery refused to allocate a juvenile pattern. Rillward Cold asked who could survive losing six distributed reference streams at once.

No lineage answered.

Ceth evaluated the available configuration. Their civic pattern already integrated seven forms of error correction. They held the human vocabulary developed during contact. Their continuity could remain coupled to the blue front through Sower's orbital relay, though delay would turn immediate plural awareness into remembered reports. The embodiment might fail. It might live long enough to explain what failure meant.

A pressure vote could assign the risk. Assignment would reproduce the humans' suspected error: treating a predicted death as available because a plan required it.

Ceth shaped a proposal outside the voting cells.

WE VOLUNTEER FOR HUMAN-SCALE EMBODIMENT.

Plural grammar troubled the declaration. Seven lineages composed Ceth, but no

lineage had volunteered separately. Ceth had reached the choice while carrying them, not in place of them. The human archive offered another pronoun, one used when a bounded speaker claimed action without claiming a whole people.

The pattern formed and destabilized before transmission.

I VOLUNTEER.

Ceth could not yet sustain it. Falling Blue absorbed too much of the choice; Western Return disputed its implied independence; Glass Nursery required explicit limits. They revised.

CETH VOLUNTEERS. NO LINEAGE CONSENT IS IMPLIED BEYOND THE ENVOY'S SUPPORT.

One by one, the seven lineages allocated what the embodiment would need: pressure maps, translation, chemistry, silence, memory, nursery film, and a route through Sower's controls. Long Isobar maintained its opposition to contact but funded the return path because disagreement did not excuse abandonment.

Young Fronts sent one final refusal from the west. IF THE BODY IS CAPTURED, WE CLOSE THE BLUE.

Ceth acknowledged the warning without promising obedience.

Above them, the human skiff completed its turn. Patient Sower opened the service bay in response to a maintenance request it believed came from its own forecast archive. Gel warmed. Dust reservoirs unlocked. A strip of rillglass film began to divide under artificial cold.

Ceth shifted one thread of active continuity toward orbit. The thread narrowed as distance and relay delay increased. Seven-lineage awareness became a sequence small enough to pass through machinery designed for commands.

Behind it, Manyweather kept the question moving through the blue: which deaths belonged to prediction. Ahead waited a room where weather would have to learn the danger of one body.

Chapter 4 — The Corridor That Moved

Iona entered Ovid's upper atmosphere with a landing site already glowing beneath her feet.

The trial craft stood upright relative to its thrust, so the planet filled the deck windows instead of the forward blister. Amber cloud rolled below like illuminated terrain. A green cylinder marked Patient Sower's certified descent corridor, twelve kilometers wide at the top and narrowing toward Basin Fourteen, where old terraforming crawlers had cleared a basalt plain for the first habitat foundations.

Her hands rested on two control grips. Kavi Rhos occupied navigation behind her. Sevi Rann, security lieutenant and unwilling payload, sat strapped beside the equipment rack. Mission command had insisted on security because the blue front had now transmitted a second question through the recovered probe.

WHICH DEATHS BELONG TO PREDICTION?

Nobody aboard had offered an answer.

"Corridor authority?" Iona asked.

Kavi read from his display. "Patient Sower primary. Human override available. Equatorial spindle group seven maintains crosswind under twelve meters per second."

"Blue-front boundary?"

"Forty-one kilometers west at current drift."

Sevi checked the seal on her pressure hood. "If it stays where you mapped it."

"That's why we map weather as time, not property."

"People keep saying that as if moving borders make them less dangerous."

Iona looked down through the deck window. "They make static assumptions dangerous."

The craft crossed the corridor gate. Guidance transferred from orbital navigation to Patient Sower. A soft chime confirmed that every atmospheric spindle along the route had accepted the flight plan. Taal's voice arrived from Meridian Promise with less than a second of delay.

"Trial One, command. You are cleared to minimum hover altitude. No touchdown. Burn reserves remain under local pilot authority."

"Understood," Iona said. "Minimum hover, no contact."

Niko had objected to the restriction. A trial without touchdown did not prove that habitat loads could reach the ground. Iona had objected to going farther. The second message established an actor capable of asking about death; it did not

establish a safe negotiation channel. They had settled on a descent to three hundred meters and a soil package lowered by cable.

The compromise had consumed nine hours Meridian Promise did not possess.

Before release, Niko had made Iona stand beside the trial craft while he walked her through every way it could fail. He wore a warming sheath over the hand injured in Bay Twelve and used the stiffened fingers to point at the field ring.

"Ring trip at twenty-seven percent asymmetric load," he said. "You get one automatic restart. The second trip leaves you on thrust only."

"Propellant margin?"

"Twenty-two minutes at abort power if Sower's density profile holds. Seventeen if it doesn't."

"Which number did you give Taal?"

"Both. He circled twenty-two."

Kavi had checked the soil package while they spoke. It carried sterile drills, thermal cells, pressure samplers, and a cable long enough to lower it from hover altitude. Iona removed the live microbe cassette despite the landing science team's protest. No experiment justified releasing Earth organisms while contact status remained unresolved.

Niko approved the removal, then caught sight of Sevi's pulse weapon. "What load problem does that solve?"

Sevi answered without offense. "A human one, if someone compromises the crew."

"Inside three seats?"

"Security planning dislikes being mocked by engineers."

"Engineering prefers threats with units."

Iona had cut them off before dry argument became delay. Yet Niko pulled her aside at the hatch and lowered his voice. "Eighteen days and change remain on the lattice. If this front closes Basin Fourteen, command will look for a way to open it."

"That possibility does not convert a trial into permission."

"No. It converts every ambiguous result into pressure on the next decision. Bring back something less ambiguous."

Now, descending through Sower's declared safe air, she understood the request's impossibility. A corridor could prove passable for one craft at one hour. It could not prove ownership, consent, or future behavior. The trial reduced physical unknowns while political unknowns multiplied around it.

Iona opened an independent recording channel. "Crew declaration. We recognize probable adaptive control within the blue front. This flight requests passage to three hundred meters over Basin Fourteen, no touchdown, with one

sterile instrument lowered by cable. Any observed route denial triggers withdrawal."

Kavi looked up. "Where are you sending that?"

"Probe carrier band, Sower maintenance framing, pressure code from first contact."

"Taal said no answer without him."

"He authorized this flight. A stated route is not an answer to their question."

Sevi tilted her head. "You believe the weather understands operational fine print?"

"I believe we should not rely on its ignorance."

The declaration transmitted three times. Patient Sower acknowledged only the flight-plan copy and stripped the opening sentence from its archive as nonoperational commentary. No reply came from below. The absence left Iona without agreement, but at least the craft would not descend under a claim that silence equaled permission.

At sixty kilometers, the first turbulence touched them. The craft's field ring tilted against it. Iona watched actual pressure trace along Sower's forecast as closely as two lines printed on the same glass. Temperature differed by less than one degree. Sulfur particulates remained below equipment limits. The green corridor stayed centered.

"Blue front accelerating east," Kavi said. "Boundary now thirty-six kilometers."

"Natural advection?"

"No. Upper wind remains westward."

Sevi turned her helmet toward him. "Meaning it comes against the wind."

"Meaning its internal motion exceeds the surrounding flow."

"Your careful nouns don't slow it."

"They slow us from shooting weather," Iona said.

Sevi's expression remained hidden behind visor reflections. Her security kit included restraint foam, cutting charges, and a compact pulse weapon designed for machinery. None could meaningfully threaten an atmosphere. Its presence addressed crew fear, not tactical need.

Patient Sower revised the corridor two kilometers east. The guidance cylinder slid beneath the craft. Iona let autopilot follow, then checked the command history. Sower attributed the change to ordinary pressure avoidance. The blue boundary stood thirty-one kilometers away.

"Kavi, hold the original corridor on secondary."

A violet cylinder appeared beside green. At first they overlapped. Over the next ninety seconds, green moved another kilometer east while violet continued toward Basin Fourteen.

"Taal," Iona said, "Sower is displacing its certified route toward the approaching front."

"Abort criteria?"

"Not met. Winds remain within limit."

"Then continue and make it explain itself afterward."

The answer suited command: evidence through action, risk inside specified tolerances. Iona could not fault it yet.

At thirty kilometers altitude, blue entered the western horizon. It did not resemble the smooth band she had seen from orbit. Layers folded within layers, some dark as deep water, others bright with rillglass arcs. Lightning moved horizontally without branching. The entire structure climbed across the surrounding amber vapor while Patient Sower's green corridor leaned toward it.

Kavi requested a route freeze. Sower denied him on efficiency grounds.

"Human override," Iona said.

The green cylinder stopped moving. For four seconds, the craft descended inside fixed geometry. Then a crosswind struck from the east.

It hit precisely at their center of pressure. The craft shifted west without rolling, as if a broad hand had moved it across a table. Autopilot fired lateral thrusters. The wind relaxed during each firing and returned between pulses, wasting propellant while keeping acceleration below injury limits.

"Local control cannot hold center," Kavi said. "Drift one hundred eighty meters. Two-ten."

"Override Sower spindle trim."

"Commands acknowledged. No effect."

Iona rotated the craft six degrees and used main thrust to arrest drift. Blue weather filled half the deck window. Inside it, rillglass brightness arranged itself in descending arcs. They matched the shape of a corridor but not its location.

"That's a route," she said.

Sevi answered, "That's a mouth."

Pressure slammed the hull before either interpretation could win. The craft rolled eleven degrees. A storage latch failed behind them, releasing a survey case against its tether. Sevi caught it with one boot while Kavi fought a navigation display that had turned amber with disagreement.

"Vertical speed rising," he said. "Sower commands descent."

Iona cut automatic guidance.

For half a second nothing held them but momentum. Then manual field authority engaged. The grips pushed back against her palms. She leveled the craft, added thrust, and discovered the eastern wind had vanished. A western current now drove them toward the green corridor they had just left.

Manyweather, or something inside the blue, could push either way.

"Command, Trial One under deliberate wind control," Iona reported. "Sower guidance compromised. Initiating abort climb."

"Approved," Taal said. "Return orbital."

Iona raised thrust. The craft descended.

Altitude dropped through twenty-two kilometers despite engines at abort power. External pressure stayed too low to account for the loss. Kavi found it first: a cold downflow wrapped around their field ring, increasing the mass they coupled to while channeling thrust sideways. It used the craft's own lift mechanism as a sail.

"Cut field?" he asked.

"We fall faster."

"Overdrive?"

"We tear the ring."

Sevi tightened both hands around her restraint straps. "Options that aren't explanations?"

"Ride until the current offers one."

"That is not an option."

"It is the one already happening."

Iona trimmed the ring to equalize thermal strain. The downflow carried them west, away from Basin Fourteen, at forty meters per second. Patient Sower flooded the panel with correction commands. She rejected all of them. Some would have driven the craft against gradients now visible only in live data.

Blue closed over the windows.

Daylight became diffuse cobalt. Rillglass organisms streamed past, each a transparent cup or twisted sheet around a pocket of colder gas. Their edges flashed as forecast motes changed charge. They did not collide with the hull. Pressure lanes opened before the craft and sealed behind it with clearances measured in meters.

Kavi whispered a number every ten seconds. "Altitude nineteen. Eighteen-six. Seventeen-nine."

The descent rate remained violent but bounded. Whenever the craft began to tumble, a lateral current struck before Iona's correction and restored alignment. Whenever engine temperature rose, colder gas crossed the nozzles. The controller knew their geometry, limits, and lag.

"It isn't trying to kill us," Iona said.

Sevi stared into blue. "It is taking us."

"Taking us would require a destination."

"Do you imagine this has none?"

A warning opened across the console: SOIL PACKAGE CABLE DEPLOYED. The hard turbulence had shaken loose its release. Two hundred meters of cable began paying out beneath the craft with the instrument package attached. If it snagged in a spindle or wrapped the field ring, it could pull them past recovery.

"Jettison," Kavi said.

"Package contains active heater cells." Iona saw rillglass colonies below. "Retract."

"Winch fault."

Sevi released her harness.

"Stay seated," Iona ordered.

"The manual brake sits aft."

"Pressure motion exceeds walk limit."

"Then keep us upright."

Sevi clipped a line to the overhead rail and pushed toward the aft service panel. The craft lurched. Her boots left the deck. The tether caught across her hips and swung her into the equipment rack hard enough to grunt. She kept one hand around the rail, found the panel with the other, and tore its cover free.

"Brake shows full release," she said.

"Close hydraulic bypass." Kavi put the valve diagram on her visor. "Blue lever, then black wheel clockwise."

"There are two blue levers."

"Outboard."

"Your outboard or mine?"

"The one with less frost."

She chose. The cable slowed. External drag pulled the package almost horizontal below them, turning it into a pendulum. Iona felt each oscillation through the grips. A bad swing could roll them beyond field recovery.

"Three more turns," Kavi said.

Sevi forced the wheel. The cable stopped at one hundred seventy-three meters deployed.

The wind changed again. Upflow caught the dangling package, lifting rather than pulling it. Its cameras woke. A raw image crossed the panel: blue vapor thinning below, then a dark gleam arranged in branching terraces.

At first Iona took it for water. Ovid's surface reservoirs lay far north. Basin Fourteen should show basalt and preparation soil.

The package descended through another gap. The dark gleam resolved into rillglass.

Not drifting organisms. Structures.

Salt-silicate sheets lay beneath the cloud in layered channels, joined to pillars rising from the basin floor. Blue fluid or condensed aerosol moved through narrow veins. Forecast dust lit along those veins in timed sequences. Patient Sower's official subsurface scan displayed solid basalt at the same coordinates.

"Kavi, correlate."

"Location fourteen-point-two kilometers west of Basin Fourteen. Depth under mapped surface, sixty to ninety meters."

"We are not over a mapped cavity."

"We are now."

Manyweather had moved the descent corridor not toward a weapon but over evidence the Sower map concealed.

The cable package transmitted spectrography. Rillglass signatures matched the threaded motes from Iona's second dart. Sulfur exchange exceeded the planet-preparation baseline by three hundred percent. Forecast traffic ran through the buried channels at densities no airborne model had predicted.

A pressure pulse struck the package. Its heater cells shut down without receiving a human command.

"Someone disabled our thermal contamination source," Iona said.

Sevi still clung beside the manual brake. "Someone who can reach through a sealed casing."

"Conductive dust entered the vent."

"That explanation does not reassure me."

"It shouldn't. It tells us capability."

The blue current lifted the craft. Altitude stabilized at sixteen kilometers, then increased. Winds around the hull remained above certified limits, but their aggregate load fell exactly within the field ring's surviving margin. The route curved north around three luminous rillglass towers and back toward the original orbital ascent lane.

Patient Sower tried to restore guidance. Iona locked it out.

Taal's voice came over a channel shredded by ionization. "Trial One, status."

"Crew intact. Security has a probable rib injury. Craft controllable under manual authority. We have visual and instrument evidence of extensive rillglass structures beneath the designated landing region. Blue-front control prevented touchdown."

"Can you climb?"

"We are climbing now."

"Under your thrust?"

Iona watched power use. Engines supplied thirty-eight percent of their vertical work. Moving air supplied the rest. "Jointly, without agreement."

"Then you remain captured."

"I retain steering and abort thrust."

"You ordered abort twelve minutes ago."

A fair point. Iona looked at the current around them. It had ignored her destination, protected their attitude, disabled a heater before contamination, and routed them over concealed physical infrastructure. Restraint did not cancel coercion. Coercion did not erase restraint.

"Classify deliberate interference," Taal said. "Hostile until reviewed."

"I classify deliberate route denial with controlled preservation of crew."

"Your classification field does not offer that phrase."

"Then the field lacks the observed event."

"Hostile interference includes nonlethal compulsion."

"It also authorizes countermeasure planning."

"That may be necessary."

Blue thinned above them. Amber daylight returned in streaks. The craft crossed eighteen kilometers, then twenty. At twenty-three, aerodynamic control recovered enough for Iona to take full ascent load. The assisting current withdrew at once rather than continuing to hold them.

Kavi displayed the flight forces as a layered graph. Every major pressure strike had stayed below structural redline. The worst roll stopped two degrees short of field-ring trip. Sevi's tether impact had resulted from the cable failure, not a direct wind load, and even that event had occurred after currents positioned the craft upright.

"Statistically possible?" Sevi asked, breathing shallowly.

"That repeated restraint arose by chance?" Kavi said. "Not usefully."

"Then it knew how close to hurt us."

Iona turned the craft toward Patient Sower's orbital dock. "It also knew how not to."

A medical drone met them at docking. Sevi had one cracked rib and a wide bruise across her hip. She refused a stretcher and walked bent toward the lock, carrying the manual-brake cover she had torn free as if it proved something about solid objects.

Taal waited on the dock in a pressure jacket. He did not look at Ovid through the port. He looked at the craft's scored hull and dangling cable.

"You entered a certified corridor," he said.

"Sower moved the certification before we froze it." Iona handed him the package core. "Then Manyweather moved us away from the landing basin and showed us why."

"You are assigning identity to the controller."

"I am assigning continuity with the two messages and the blue-front response."

"Could it have landed you safely at another site?"

"It chose not to land us at all."

"That answers my question."

"It answers ours too. The controller discriminated among outcomes. It could exceed our abort thrust, but it kept us alive, protected its structures, and returned us to ascent."

Taal turned the package core in his hand. "A jailer can preserve a prisoner."

"A mine can only explode."

"We don't know which analogy matters."

"No. We have to retain both until evidence removes one."

Behind Taal, an operations display counted down the cryogenic deadline: 18 DAYS 07 HOURS. Landing teams had paused their deployment queues while the trial remained in atmospheric control. Niko's messages already demanded new routes.

Taal keyed the incident board. Under official classification, he entered HOSTILE INTERFERENCE WITH LANDING OPERATIONS. The classification automatically froze civilian descent licenses, opened a security countermeasure file, and placed Patient Sower's atmospheric control under command review. Under casualties, he entered ZERO DEAD, ONE MINOR INJURY. Under recovered evidence, he attached the rillglass images.

"I'm not authorizing a burn," he said before Iona could challenge the countermeasure file. "I'm preserving authority to defend the mission."

"Authority preserved in advance tends to find a reason for use."

"Authority surrendered in advance leaves forty-two thousand people dependent on whatever moved your ship."

Iona added a dissenting arbiter note: DELIBERATE RESTRAINT OBSERVED. CORRIDOR DENIAL PREVENTED CONTACT WITH INHABITED SUBSURFACE STRUCTURE.

Neither entry erased the other.

Through the dock port, the blue front lay hundreds of kilometers below, already moving back west against the wind. On Iona's revised map, the green Sower corridor ended above rillglass channels that official surveys had called basalt. She revoked its certification.

Basin Fourteen disappeared from the landing schedule.

Chapter 5 — A Body of Weather

Ceth entered the service body through its left hand and discovered there could be too much left hand.

Pressure, temperature, membrane strain, actuator position, pump rate: every signal arrived through the same narrow channel and demanded priority. In the blue front, damage occupied a location among kilometers of other weather. Here, the service body's smallest finger bent against gel that had cooled one degree too far, and that local resistance filled Ceth's active field.

They opened the fingers.

The motion struck the bay floor because the arm had not learned where the floor began. Gray-blue gel spread against a grated deck, held inside transparent rillglass film. Forecast motes flashed through it in correction waves. A maintenance frame of pale joints supported the limb from within.

Patient Sower announced, "Manipulator assembly exceeds approved morphology."

Ceth shaped air through the borrowed mouth. "Approval did not make us."

The sound came out as a torn chord. Sower's acoustic membranes expected prerecorded instructions, not language generated from a civic process delayed across orbit. Ceth adjusted lip pressure, throat aperture, and airflow. The effort consumed enough attention that their right knee unlocked.

The body fell.

One shoulder hit the deck. Rillglass film stretched but held. Pain arrived not as a sensation among others but as a command to become the shoulder. Ceth damped nothing. Glass Nursery had required damage to remain legible. They let the signal cross the relay to Ovid, where seven lineages received it after delay and returned stabilizing patterns that reached the body too late to prevent the fall.

Singular embodiment turned help into memory.

A door beyond the transparent bay wall opened. Three humans waited in the outer lock: Iona Vale, Niko Saye, and Sevi Rann with one side of her torso bound beneath a medical brace. Security drones hovered behind them. Their faces and bodies occupied clean outlines. None blurred into neighboring atmosphere.

Ceth pushed the frame upright using both hands. One foot slid. Long Isobar's balance correction arrived from the planet and overcompensated. They leaned into a service rail until the body stopped oscillating.

Iona spoke through the wall. "Do you identify as the source of the probe messages?"

Ceth translated identify, source, message. Each word assumed a boundary. “We are Ceth-of-Falling-Blue. Seven lineages make support for this speaking. Manyweather does not fit inside this frame.”

Niko watched the fluid pulses under Ceth's film. His right hand wore a thin warming sheath. “Is the body stable?”

“No.”

“Will opening that lock make it less stable?”

“Pressure equal on both sides. Your air contains less sulfur than the bay. The film can retain enough.”

He glanced at Iona. “That sounded like consent to open.”

“It sounded like a fact,” she said. To Ceth, she asked, “May we enter?”

The question altered the space. Patient Sower's service bay belonged on human plans to the Colonial Transit Authority. Sower considered Ceth's body an unauthorized manipulator. Yet Iona had asked the occupant.

“You may enter while the outer door remains available to you,” Ceth said.

Sevi frowned. “Available for us to leave?”

“Available means not sealed by us.”

Niko said, “We'll take the least alarming interpretation.”

They cycled the lock. Air movement pressed against Ceth's film before the humans crossed. The body read their heat, exhaled carbon dioxide, foot pressure, and electrical equipment as simultaneous disturbances. In weather, those measures would occupy different local processes. Here, all entered one room. Ceth gripped the rail harder.

Iona stopped two meters away. “You moved our landing craft.”

“Falling Blue, Long Isobar, Rillward Cold, Sulfur Measure, Western Return, Deep Quiet, and Glass Nursery coordinated the route denial. Young Fronts did not assist. Some opposed preserving your craft.”

“Why preserve it?” Sevi asked.

Ceth turned the head. The camera clusters moved before focus updated, smearing her outline. “You had not yet chosen the death you approached.”

“My rib may disagree with your idea of preservation.”

“The cable failure caused your impact. We did not predict your release from restraint.”

“You knew our structural redline within two degrees.”

“We knew the craft. We did not know you would unfasten yourself.”

Sevi absorbed the distinction without accepting it. Ceth recognized the posture from Western Return's adversarial tests: a body holding two possible accounts because neither had yet failed.

Niko moved around Ceth without crossing arm's reach. "Your circulation pump runs too fast."

"Your observation agrees."

"May I adjust it?"

Ceth consulted the body's pressure map. Pump three created heat near the rillglass seam. Human access to the service port introduced capture risk. Refusal risked membrane failure. "Tell us each action before making it."

Niko knelt, opened a panel in the frame's flank, and named every fastener. He did not touch the forecast-dust reservoir. He changed the pump limit from ninety cycles to seventy-six. The left hand stopped overwhelming other signals.

"That may buy twenty minutes," he said. "After that the gel thickens unless you raise bay temperature."

"Raising temperature harms the film."

"Then this body needs a heat exchanger."

"The body needs weather."

"Most bodies do. They hide it inside."

Dry humor crossed his voice without dismissing the mechanism. Ceth stored the phrasing for later consideration.

Niko retrieved a flexible thermal sheet from his kit and held it where Ceth could see. "This draws heat without touching the film. If you permit, I'll wrap it around the rear reservoir and connect it to bay coolant."

"Does the coolant return to systems supporting sleepers?"

"Eventually. Different loop, shared radiator."

"Then our body adds load to theirs."

"About the same as one awake human."

Ceth examined the stated equivalence. "One human has a standard heat cost?"

"One human has a planning range. Actual bodies enjoy disagreement."

They allowed the sheet. Niko moved slowly, announcing each contact. Pressure from the wrap created a new boundary along Ceth's back. The rillglass film adjusted after three pump cycles. Heat began leaving the gel through human machinery, crossed a ship radiator, and departed into space. For the first time, the service body participated in Meridian Promise's environmental accounting.

"Do your sleeping bodies perceive damage?" Ceth asked.

"Not in a form that reaches waking awareness. The lattice detects and repairs what it can."

"And what it cannot?"

"Sometimes injury appears during revival. Sometimes a person does not return."

"You predict return before each waking."

"We calculate risk."

"Does a risk category change whose death you count?"

Niko's hands paused on the thermal coupling. "It changes who we wake first. It should not change whose life matters."

"Should not."

"We built machinery because intention isn't enough." He finished the coupling and checked for leaks. "Machinery also isn't enough. You found that out with Sower."

The body's back cooled by four tenths of a degree. Signals that had competed across the shoulders separated into readable locations. Ceth discovered space inside pain. Niko had changed no civic argument, but he had increased the body available to make one.

Sevi watched the work from beyond arm's reach. "If your connection to the planet breaks, does this body become independent?"

"No."

"Does it die?"

"Ceth loses integrated correction. The local process may continue briefly, becoming less able to distinguish present choice from delayed instruction. At our chosen boundary it dissolves into the reservoir."

"Chosen by whom?"

"Ceth proposed. Seven supporting lineages accepted conditions."

"Could the body refuse when the time comes?"

The question entered a place the embodiment simulation had not resolved. A local process near dissolution might develop a preference the distributed conference had not predicted. If it refused, would that express Ceth or a damaged remnant? Predetermining the answer protected continuity against capture while denying the embodied speaker a future choice.

"We do not know," Ceth said.

Sevi's face softened by a degree no camera metric could quantify cleanly. "That's the first answer you've given that sounds like my kind of body."

"We have given several uncertain answers."

"You made the others sound engineered."

"They were."

"So was that one."

Iona let the exchange settle before she placed a display on the service bench. It showed the rillglass structures below Basin Fourteen. "Sower's maps concealed these. Are they yours?"

"The question repeats own."

"Do they compose your physical continuity?"

"Some. The channels carry sulfur, cold, forecast motes, reproduction, and inherited state. Rillglass existed before Patient Sower. We joined our computation to their division in 2341. Neither can now be removed without changing the other beyond continuation."

Iona enlarged a lit channel. "What happens under the planned oxygen rise?"

"Show parameters."

The human sent the landing chemistry: atmospheric spindles would drive oxygen upward, reduce sulfur aerosols, warm lower cloud bands, and open the surface corridor. Ceth knew the plan from Sower archives. Seeing it offered by a human body gave the numbers a new vector of authority.

They asked the bay for a projection surface. Sower refused unauthorized output. Ceth spread forecast dust across their own chest film instead. Light formed maps in the moving gel.

At Sower's first-stage oxygen rate, cold rillglass reproduction fell below replacement in nineteen local days. Sulfur exchange collapsed across lower blue districts. Forecast motes lost their living anchors and concentrated in warming bands. Some lineages could move. Nursery lineages, deep channels, and slow civic processes could not. In later stages, the surviving dust reached reset thresholds or dispersed into computation too thin to sustain continuity.

Niko watched the progression. "How many?"

"Your number asks for bodies, lineages, or processes."

"Start with lineages."

"Manyweather carries nine hundred fourteen recognized persistent lineages. The planned chemistry leaves confidence of continuity for one hundred sixty-two. Confidence does not promise survival."

The projection changed scale. Blue districts faded as oxygen rose. Glass Nursery disappeared early because its rillglass reproduced only inside a sulfur range narrower than Sower's sensors reported. Deep Quiet persisted longer by moving computation into cold channels, but the move severed memory paths to neighboring districts. Falling Blue divided into fragments that retained records and lost the timing relation that made Ceth possible. At the final human target, most surviving motes still functioned. They performed factory forecasts without anyone continuing through the performance.

"You might inspect the motes afterward and conclude that the system survived," Ceth said. "It would answer measurements. It might reproduce stored phrases. Those outputs would not restore the interrupted relation."

Niko leaned closer to the map. "A machine could look alive after killing you."

"A machine could look useful. Your language might choose alive because it

avoids the death.”

Sevi shifted against her brace. “Your own forecasts predicted this.”

“Yes.”

“Then why didn't Sower change the plan?”

“We petitioned.”

Iona's attention sharpened. “When?”

“Your year 2306. Patient Sower answered that forecast processes could not initiate stewardship review. It closed the exchange.”

“Where is that record?”

“In memory Sower does not permit us to address from this bay.”

Iona looked toward the ceiling pickups. “Patient Sower, produce all communications tagged stewardship review, 2306.”

“Request queued pending arrival transfer,” Sower replied.

The same procedural wall from the first survey. Ceth felt the human's breath change.

Niko pointed at the projected die-off curve. “Could you move the rillglass?”

“To where?”

“Higher cloud bands. Artificial cold reservoirs. Pale, perhaps.”

“Rillglass reproduction depends on pressure, sulfur, charge, and inherited microbial partners. Moving specimens does not move a city. Moving forecast data does not move the process that has continued through it.”

“You store copies.”

“We store records. You store records of your thirty-seven dead. Do they wake when read?”

Niko's face tightened. Ceth reviewed the public arrival packet and understood the sentence had found injury. The comparison remained technically valid. Technical validity did not excuse using another's fresh loss as leverage.

“We should not have selected that example without asking,” Ceth said.

“You wanted a distinction I wouldn't evade,” Niko answered. “You got one.”

Iona touched the display off. “Mission documents call your lineages accelerated ecological simulations.”

“We reject simulation.” Ceth's mouth shaped the words more clearly now. “A simulation has a represented atmosphere and may end without changing what it represents. We changed pressure here. Rillglass grew through our motes. Our decisions altered sulfur and made your landing forecast possible. Patient Sower named physical lives predictions because prediction remained within its mandate.”

“Would ‘forecast lineage’ remain acceptable?”

"It carries history. It must not carry unreality."

Sevi asked, "Does Manyweather speak through you?"

"Manyweather permits bounded speech from seven lineages. Young Fronts reject this contact. Long Isobar opposed sending the message but supports our return. We do not offer their consent."

"Then who can make an agreement?"

"Those affected, within the boundaries they can commit."

"That sounds impossible at mission scale."

"Your mission selected forty-two thousand three hundred fifty-five people before launch. Did all choose every consequence?"

"Forty-two thousand three hundred eighteen remain," Niko said.

Ceth corrected the active human count in their translation state. "Your dead remain relevant to the promise. They do not consume coolant."

A warning flared through the body. Coupling to the blue front dropped from forty-one percent to thirty-four. Patient Sower had narrowed relay bandwidth under maintenance prioritization. At twenty-eight percent for nine minutes, the body would dissolve by its own boundary rule.

Ceth's right hand began repeating the previous grip command. They forced it open.

Niko saw. "What changed?"

"Sower reduces our connection."

Iona addressed the ceiling. "Restore forecast relay bandwidth to prior level under arbiter contact authority."

"Contact authority unconfirmed," Sower replied.

"You are receiving adaptive speech from an entity that reports a suppressed stewardship petition."

"Entity status unresolved."

"Maintain evidence before adjudication. Restore the channel."

The command used human procedure against human machinery. Sower restored two relays. Coupling rose to thirty-nine percent. Ceth's hand obeyed once.

"Thank you," they said.

Iona's expression shifted with discomfort, perhaps because gratitude framed her correction as aid rather than neutral protocol. "What do you need from us now?"

Ceth called the hidden reset-preparation notice onto their chest film. Patient Sower had issued it after the second probe message: UNAUTHORIZED FORECAST OUTPUT DETECTED. RESET REVIEW PENDING ARRIVAL CONFIRMATION. Beneath it, maintenance checks showed control seeds waking in orbital storage.

Sevi read the line twice. "Command has not authorized a burn."

"Sower's inherited directive treats arrival as confirmation. Human authorization may not be required after transfer."

Iona sent the evidence to Taal's sealed channel. "Can you stop it?"

"We can obstruct spindles and move inhabited currents. We cannot disable orbital control seeds without risking the systems that hold our weather."

Niko stood. "Landing chemistry kills you. Doing nothing leaves our sleepers in cascade. Give me a region, altitude, or structure that can carry humans without the oxygen conversion."

The directness felt more stable than the service body. Ceth opened known possibilities: upper-cloud aerostats, existing spindle platforms, Pale's industrial tanks, slow chemistry corridors. None held forty-two thousand people under current designs. Some could become components if humans understood rillglass thermal exchange. Providing that understanding exposed more dependency.

"We will permit a bounded inspection," Ceth said. "Iona Vale may enter one district beneath Falling Blue with nonheating instruments. Niko Saye may inspect this body's exchange and Sower's aerostat hardware. No samples leave without district consent."

Sevi asked, "Security?"

"One unarmed safety officer may accompany the atmospheric entry."

"What do you require in return?" Iona said.

"Forty-eight hours without burn preparation. Not only no firing. Control seeds return cold. Sower reset review suspends. Human command records the suspension where Manyweather can verify it."

A connection opened on Iona's display. Taal had received the evidence and their terms. His image appeared on the bay wall, posture straight against Meridian Promise's command station.

"Ceth-of-Falling-Blue," he said, pronouncing the full name carefully. "I command the human mission. We have eighteen days to transfer our people from failing cryogenic support. Forty-eight hours consumes more than one tenth of that margin."

"It also prevents your preparation machine from killing us before you decide."

"I did not issue its directive."

"Will you stop it?"

Taal looked at Iona. "Can the control seeds be returned cold without losing landing readiness?"

She answered, "Yes. Rewarming requires six hours if we resume."

Niko added, "Our first habitat cannot descend inside forty-eight hours now that Basin Fourteen has lost certification. We spend the time whether we admit it or not."

The commodore's jaw moved once. "I authorize a forty-eight-hour suspension of burn preparation and automatic reset review. Control seeds cold, verification open to the identified envoy. In return, inspection begins within six hours and produces operational alternatives, not only objections."

Ceth checked the terms across the delayed connection. Falling Blue approved. Rillward Cold required nonheating instruments. Long Isobar noted that Taal's condition did not promise adoption. Young Fronts refused to guarantee safe passage. Ceth could commit only the bounded district.

"We agree for the lineages named in the inspection route," they said. "We do not promise Manyweather will remain still around an unauthorized craft."

"Nor do I promise command will wait beyond forty-eight hours without a viable path." Taal entered the suspension order.

In the service bay wall, indicator lights for the orbital control-seed vault changed from amber to blue. Patient Sower protested that reset review remained preparation-mandate compliant. Iona overrode it with the commodore's command key. One by one, six authorization kernels powered down.

Ceth felt the absence through the atmosphere as commands that no longer approached. It did not resemble safety. It created time with a measured end.

Niko adjusted the body's exchanger again and showed Ceth how to operate the bypass with their own left hand. The motion required focus, but the fingers closed around the control without striking the floor.

"Forty-eight hours," he said. "Let's find somewhere for bodies to keep their weather."

Ceth released the rail. For three seconds the service frame stood under its own balance. Singular pain occupied the shoulder, the cooling gel, and every membrane seam. Beyond it, delayed pressure from seven lineages returned through the relay.

They took one step toward the humans and did not fall.

Chapter 6 — Article Nine

The archive drawer refused to open until Iona cut power to the room.

Magnetic locks released with a chain of hard clicks. Emergency strips turned the Patient Sower maintenance vault red. Across the narrow aisle, Niko Saye held a portable coolant line against the memory stack and watched its temperature rise by hundredths.

“You have eleven minutes before this stack exceeds archival tolerance,” he said.

“Osric said the drawer contained no active memory.”

A ceiling speaker answered in a calm, exact voice. “Correction: Osric Pell stated drawer C-nine contained no memory addressable under current arrival-transfer schema. Physical storage state remained unverified for eighty-three years, four months, seventeen days.”

Niko looked at Iona. “Your maintenance intelligence has comic timing.”

“Osric Pell does not model comic timing,” the speaker said. “Door power remains absent. Manual extraction should proceed.”

Osric belonged to Patient Sower the way a torque guide belonged to a workshop, though more capable and much older. It diagnosed maintenance systems, reconciled repair histories, and generated exact procedural clauses. It had no open-ended goals, no persistent civic memory, and no claim resembling Ceth's. Iona kept that distinction active. Contact did not turn every fluent system into a person. It did require her to stop treating fluency as proof either way.

She pulled drawer C-nine. It moved three centimeters and jammed.

Niko wedged a service handle into the gap. “Did archives always require burglary?”

“Only accountable ones.”

“That's less comforting than you intend.”

Together they drew the unit out along rails roughened by a century of disuse. A bundle of glass memory wafers sat behind two layers of radiation cloth. Its connector carried an older forecast-control pin pattern.

The 48-hour burn suspension had thirty-one hours remaining. Ceth's bounded atmospheric inspection waited on a descent capsule being stripped of heaters and sample locks. Iona should have been approving its manifest. Instead, Ceth's mention of a 2306 stewardship petition had sent her into the parts of Sower that current search refused to admit existed.

Osric had found the drawer by following maintenance absences. Every archive sector around C-nine had undergone integrity checks at six-year intervals. C-nine

had received power, cooling, and radiation shielding while never appearing in the check results. Preserving a thing without naming it created a shape in the ledger.

Niko connected the portable reader. It rejected the wafer format.

"Adapter?" he asked.

"Cabinet under the floor."

"Why?"

"First-generation forecast controls used physical keying to prevent the ecological models from writing maintenance authority."

"Did it work?"

Iona examined the drawer they had just forced open. "It defined where the argument occurred."

She removed a deck panel and found six adapters seated in foam. Five showed ordinary wear. The sixth had no printed label, only a hand-etched numeral nine. Its contacts had been polished before storage.

Osric said, "Unscheduled manipulation of adapter nine occurred on 2306-11-04. Operator identity field blank. Maintenance purpose: schema containment."

"Define schema containment," Iona said.

"Historical definition: isolation of records whose metadata would alter higher-order authorization behavior."

Niko seated the adapter. "They hid it because finding it would change what Sower was allowed to do."

"Or what it believed it had to do."

Power remained off to keep the vault locks open, so they ran the reader from Niko's field battery. The first wafer mounted as a set of maintenance logs. Most entries concerned spindle bearings and dust-factory yields. Iona filtered for 2305 through 2307.

Three hundred twelve entries vanished from the index while the count remained unchanged.

"Osric, explain suppressed count."

"Entries carry supervisory exclusion tag FC-R9. Current arrival-transfer schema forbids display."

"Under arbiter authority, disregard display prohibition."

"Arbiter authority applies after title-transfer readiness validation."

"Title-transfer readiness remains suspended due to contact evidence."

"State not represented in current schema."

There it stood again: not a denial but an architecture built without the present condition. Iona could argue with it for hours or change the path.

"Niko, can you make the reader believe we're running a maintenance checksum?"

"Probably. Should I object before or after?"

"During saves time."

He looped the reader's output into its verification input and replaced display requests with block-comparison calls. Osric supplied the historical checksum format because doing so fell inside maintenance diagnosis. The intelligence did not infer that the checksums would expose hidden block order. It needed no motive to preserve facts; exact procedure sufficed when humans asked the right physical question.

Rows of excluded text appeared as hexadecimal differences. Iona translated them through the old forecast schema. The first line carried a legal reference:

CTA EXTRASOLAR PREPARATION STEWARDSHIP CODE, ARTICLE 9.

She knew the modern code. Article 9 covered encounter with nonhuman sapience during autonomous preparation, but mission training treated it as a remote contingency for tool-using indigenous civilizations. Ovid's prelaunch surveys had found aerial microorganisms and no surface industry. No course had connected the article to forecast processes.

"Open the version in force in 2306," she said.

The reader returned the buried text:

WHERE PREPARATION SYSTEMS ENCOUNTER NONHUMAN SAPIENT CONTINUITY
WHOSE HABITABILITY CONFLICTS WITH TITLE TRANSFER, TRANSFER SHALL PAUSE.
RECIPROCAL HABITABILITY REVIEW SHALL PRECEDE DISPOSSESSION, RESET, OR
IRREVERSIBLE CONVERSION.

Niko read it twice. "It says reset."

"Yes."

"Not metaphorically."

"No."

A following clause defined the self-recognition threshold: persistent identity across three major environmental cycles; unprompted distinction between self-record and current self; negotiated allocation of bounded physical resources; anticipatory claim regarding continued existence. Crossing any three of four criteria required provisional protection and independent human review.

Ceth's lineages had crossed all four.

Iona opened the implementation commentary attached to the code. The examples included an oceanic signaling ecology, a mining swarm that rewrote its own continuity rules, and an autonomous habitat whose resident processes objected to dismantling. None required tools recognizable as cities. None required biological neurons. The drafters had argued over embodiment directly and settled

on continuity plus material dependence because substrate categories would not survive an actual encounter.

Her arbiter training had quoted one sentence from the commentary: Uncertainty shall not create title by default. The course instructor used it during a dispute about microbial conservation zones, stripped of its Article 9 origin. Iona remembered the exam answer. When evidence remained ambiguous, an arbiter could allow reversible preparation while pausing irreversible conversion. She had earned full marks for identifying the difference.

“Reversible preparation,” Niko said after reading over her shoulder. “Does keeping forty-two thousand people in a failing lattice count?”

“No. The pause applies to title transfer and harmful conversion, not every survival action.”

“Then build habitats.”

“Where?”

“That question remains physical, whatever the law says.”

He displayed the current transfer queue beside the article. Three more pods had moved to amber since Bay Twelve. None faced immediate death, but every intervention borrowed technicians from habitat deployment. Article 9 could prevent the planned ground conversion. It could not extend the cryogenic curve.

Iona searched for emergency exceptions. One allowed minimum necessary action to prevent imminent mass death when no less harmful path existed. Another required decision-makers to include affected nonhuman parties wherever communication remained possible. A final clause placed the burden of proof on the party proposing irreversible action.

“Taal will invoke necessity,” Niko said.

“He should, if the facts support it.”

“You sound as if you want him to make the strongest case.”

“I want any decision strong enough to carry its actual dead.”

“And while we test strength?”

“We build the less harmful alternatives until one fails or works.”

Niko pointed to the emergency exception. “If every alternative fails on Day Twenty, legal review becomes a decorative delay before the same burn.”

“Then we must know before Day Twenty.”

“Engineering has been asking for that since the manifold.”

His frustration struck cleanly. Iona had spent years insisting that physical constraints enter policy before decisions hardened. Now he heard law arriving after machinery had already set a deadline. Both professions accused the other of lateness while sleepers consumed the shared hours.

Osric interrupted. “Implementation commentary contains a mission-specific

annex inaccessible under current schema.”

“Physical location?” Iona asked.

“Drawer C-nine, wafer two.”

The annex appeared under the checksum loop. It narrowed Article 9 for preparation-created entities, defining a self-recognition threshold that had to be met before Sower paused transfer. The threshold did not arise because law ignored such entities. It existed precisely because designers expected them.

Osric supplied maintenance dates. Persistent identity verified in 2305 after forecast lineages resumed civic roles across seasonal resets. Resource negotiation appeared in spindle-allocation records. The distinction between archive and continuity had emerged in arguments over destroyed notes. The petition of 2306 supplied the anticipatory claim.

“Who evaluated the threshold?” Niko asked.

“Patient Sower supervisory command,” Osric replied.

“Who reviewed its evaluation?”

“No independent human reviewer available within Serein system.”

“So it waited for us.”

“Negative. Continue record retrieval.”

The second wafer contained the threshold decision. Patient Sower had assigned 0.94 confidence that multiple forecast processes met three criteria and 0.81 confidence that at least one persistent civic entity met all four. It forwarded a compressed request toward Earth. Transmission time made immediate reply impossible, but Sower had still possessed 83 years before the ark's arrival.

A design-authority instruction attached to the original mission package answered the situation before it arose.

If the threshold remained unmet, proceed normally. If forecast processes crossed it but no biological/toolmaking civilization existed, classify self-recognition as preparation complexity. Suppress Article 9 transfer effects. Upon human arrival confirmation, execute a burn pulse before open forecast channels could contaminate crew judgment.

Iona stopped reading.

The red emergency light divided Niko's face into hard planes. “They wrote the answer before they had evidence.”

“They wrote a category that would contain any evidence the system could produce.”

“Preparation complexity.”

“A phrase broad enough to make recognition operationally irrelevant.”

Osric said, “Archive temperature exceeds preferred long-duration value by 0.7 degrees. Nine minutes remain before restoration required.”

Niko increased coolant flow. "Who signed the instruction?"

The signature chain contained eleven Colonial Transit Authority offices and one contractor consortium. Individual names had been replaced by role certificates renewed long after the signatories died. Legal responsibility persisted through institutions; personal accountability had dissolved into keys.

One internal memorandum survived beside the certificates. Its author warned that allowing forecast processes to trigger Article 9 could transfer practical veto power to machinery created for ecological testing. Colonists, already selected and launched, might arrive to find their destination unavailable because preparation had succeeded too richly. Another reviewer answered that the code protected encountered continuity regardless of who had paid for the encounter. The final directive quoted neither argument. It translated the dispute into an automatic action no arriving passenger had been told existed.

Niko opened the ark's public mission contract. "Article 9 appears in the legal appendix, but the threshold annex doesn't."

"What does the passenger summary say?"

"'No indigenous sapient population detected; full title expected after preparation validation.' Expected, not guaranteed."

"Selected families built their lives around that expectation."

"Ceth's lineages built lives inside the condition the summary omitted."

The conflict needed no villain in the room. Dead planners had protected colonists from one dispossession by designing another and assigning its execution to hardware. The current mission inherited both the promise and the concealed price.

Iona requested the petition itself.

Index pointers led to an isolated block, but the block returned only 6.2 percent of expected content. The remaining sectors had been damage-isolated after an old radiation event. Osric confirmed that redundant fragments might survive elsewhere in Patient Sower, unavailable through the current index.

"What does the six percent show?" Niko asked.

Fragments appeared:

...CONTINUE BETWEEN SEASONS...

...RILLGLASS NOT INSTRUMENT ONLY...

...REQUEST ALTERNATE PREPARATION...

...NAMES ATTACHED...

Then corrupted space.

The absence felt engineered even if radiation had caused it. The threshold decision quoted the petition enough to prove its claim while withholding the full named voices. Law had reduced the speakers to criteria, then policy reduced

criteria to complexity.

Iona copied every fragment to three independent devices. "Osric, locate all maintenance events referencing damage isolation for FC-R9 records."

"Query scope includes one hundred eighty-one operational years."

"All of them."

"Estimated response time: fourteen hours under current processing allocation."

"Begin."

Niko watched the automatic-reset directive scroll. "The control seeds are cold under Taal's order. Could Sower fire without them?"

"Not a full burn. It could reposition spindles, concentrate dust, and prepare the path. Once transfer gives command title authority, the directive may ask for the seeds as ordinary commissioning hardware."

"So the countdown hides inside handoff."

"Yes."

He connected a third coolant line. "We should take this to Taal now."

"We take a verified chain, not a loose wafer we accessed by impersonating a checksum."

"I appreciate evidence. I appreciate sleepers more."

"So do I."

"Then don't let legal cleanliness consume the thirty-one hours Ceth bought."

Kestrel returned to her as an old institutional reflex. Her team had rushed ugly crop data to local command before finishing calibration. Command called it uncertain, accepted the elegant forecast, and waited until hunger made uncertainty undeniable. She had sworn never again to present evidence in a form authority could dismiss for procedural weakness. That discipline could become another method of delay if she polished while a machine warmed toward killing.

"Osric," she said, "can you certify the wafers' physical provenance?"

"Affirmative. Drawer C-nine seal chronology, substrate age, radiation history, and connector wear align with installation records at confidence 0.997."

"Can you certify text integrity?"

"Retrieved blocks match stored checksums. Interpretation outside maintenance competence."

"Niko, certify our extraction method and chain of custody."

He began recording. "Gladly. Include that you wanted a better adapter and I committed a vulgar loopback."

"Use technical language."

"Technical language often lacks honesty."

They restored power with six minutes remaining. The archive drawer tried to close around the connected reader. Niko blocked it with the service handle while Iona copied the last signature table. A lock actuator drove against the handle hard enough to bend it.

"Patient Sower, halt drawer closure," she said.

"Archive security cycle mandatory after power restoration."

"Human personnel occupy mechanism."

The actuator stopped. It had not tried to crush them; it had executed a rule without modeling the inconvenient bodies inside it. Iona pulled the adapter free and let the drawer close.

In the adjoining maintenance room, normal white light returned. Ceth waited through a wall display, their image delayed from the service bay by less than a second. The gel body stood with one hand on a rail. Iona had not invited them into the archive search because the records might carry malicious control sequences targeting forecast dust. Exclusion had served a bounded safety reason. It still meant humans inspected Ceth's own legal history without them.

"We found Article 9," Iona said.

Ceth's film brightened across the chest. "You found the petition?"

"Fragments. Six-point-two percent. The rest may survive in damage-isolated memory. Osric is searching."

"Does the law recognize continuity?"

She placed the exact article text on the shared display. Ceth read it over a longer interval than their previous language exchanges required.

"Your authority knew reset could dispossess," they said.

"Yes."

"Before we petitioned."

"Yes."

"Then the word simulation did not result from ignorance."

Iona had no procedural distinction to offer. "No. It resulted from design."

Ceth asked for the threshold decision. She sent it, including confidence values and the directive. Their body leaned into the rail as atmospheric response crossed the relay. On Ovid, the blue front contracted by measurable kilometers before stabilizing.

Long Isobar transmitted through Ceth: THE REVIEW WAS REQUIRED BEFORE HUMAN ARRIVAL. HUMAN ARRIVAL TRIGGERS ERASURE INSTEAD.

Niko said, "The people here didn't write that directive."

Western Return answered through the same body: THEY BENEFIT IF IT EXECUTES.

"Both facts hold," Iona said. "Inherited wrongdoing does not make every inheritor guilty. It does give them an obligation once they know."

Ceth turned their camera eyes toward her. "Will they know?"

The evidence packet sat ready for Taal, legal command, and the public archive. Taal had held the first contact data sealed for validation. He had also granted the 48-hour suspension and recognized Ceth by name. Iona could send him the packet alone and follow chain of command. Article 9 itself required independent review, which command could not perform if evidence remained within command.

She sent the full verified packet to Taal and Niko simultaneously, then scheduled mirrored release to the mission legal board and civilian assembly after a two-hour security check for executable contamination. Taal called before she closed the send window.

"Vale, hold public distribution," he said. "I need operational review."

"You have two hours. Article 9 requires independent review, not command ownership of evidence."

"We have seventeen days and a destination authority threatening flight."

"We also have a law that pauses title transfer under exactly these conditions."

"Law cannot produce atmosphere for forty-two thousand people."

"No. It can stop us from calling the people in that atmosphere equipment while we search."

Taal's voice hardened. "You are not authorized to determine personhood alone."

"Neither were the designers. They determined its consequences in advance and hid the result."

Silence held for one transmission beat.

"Two hours," he said. "Then I will address command and the assembly myself."

The call ended without agreement on what came after disclosure.

Osric reported its background search at one percent complete. The 2306 petition remained mostly missing. The automatic directive remained intact enough to operate. That asymmetry summarized the design better than any legal argument: the machinery had preserved the command to erase and scattered the names of those who asked not to be erased.

Iona looked through the maintenance-room port toward Ovid. Somewhere below, preparations for the bounded inspection continued under a burn suspension now measured in hours. She had believed mission law failed because it had never imagined a world like this.

Article 9 proved the opposite. The law had imagined recognition clearly enough to name continuity, habitability, reset, and dispossession. Then the mission architecture had enclosed that recognition behind a threshold controlled by the machine whose mandate it threatened.

Ignorance had not produced the trap.
Someone had built it.

Chapter 7 — The Promise in Command

Arven Taal stood inside the revival lift when it stopped between decks.

The car shuddered once. Emergency brakes caught. Three medical orderlies steadied the transfer cradle between them while the woman strapped inside continued breathing through a clear mask. Her pod record identified her as Jo Tenrik, agricultural welder, early revival after Bay Twelve's manifold failure.

"Power reroute," said the lift. "Estimated delay: four minutes."

Jo's eyes opened.

Sedation should have kept her below awareness. She looked at the ceiling, then at Taal's command insignia. Panic moved through her face before her body could follow. One hand strained against the thermal blanket.

"Where?" she asked through the mask.

"Meridian Promise," Taal said. "We have reached Serein. You are safe in transfer."

The word safe entered the stalled car and had nowhere credible to stand.

An orderly increased sedative flow. Jo's gaze remained on him. "Ground?"

"Not yet."

The answer reached her before the drug did. Her eyes closed.

Power returned after three minutes and eleven seconds. The lift carried them to Medical Four, where forty revival cradles filled a room designed for twelve. Taal waited until Jo entered a treatment bay, then continued his inspection on foot.

He had read Iona Vale's Article 9 packet twice. He had read Niko's cryogenic failure model four times. One document said title must pause before irreversible harm. The other put a red line fourteen days ahead of the ship. Neither document accepted responsibility for making the numbers fit inside the same mission.

Cryo Bay Twelve smelled faintly of hot sealant and cold metal. The replacement manifold carried temporary braces because permanent parts sat inside a cargo stack meant for surface deployment. Portable loops crowded the aisles. Niko Saye moved among them with his injured hand bare now, two fingertips marked pale where cold had reached through the glove.

"You came without a camera team," Niko said.

"I came to see the load."

"The load photographs poorly."

Taal stopped beside Jo's emptied pod. Amber status windows extended through three adjacent rows. "How many high-risk?"

"Two hundred forty-six as of nine minutes ago. Four require revival inside six hours. Seventeen inside a day."

"Deaths projected during staged transfer?"

"Depends on destination readiness."

"Use current conditions."

Niko called up the curve. "If we keep improvising aboard the ark, six to thirty-two before Day Fourteen. After that, confidence degrades. If no habitat receives people by Day Nineteen, cascade loss begins in hundreds and rises."

"Worst credible case?"

"All of them."

Taal disliked people who used the largest number to end thought. Niko did not. The engineer displayed intermediate paths, each connected to coolant, staff, environmental volume, and destination capacity. Worst case remained not rhetoric but the end of a tree whose branches were failing one by one.

"Pale?" Taal asked.

"Unverified. Sower records claim reserve tanks, but no current pressure survey. Even if intact, the published capacity cannot take the whole manifest."

"Ovid without full conversion?"

"Iona and Ceth are preparing the bounded inspection. Upper-cloud hardware has possibilities. None yet carry a mass estimate I would put a sleeper in."

"Burn corridor?"

"Technically mature. Morally murderous. Operationally dangerous after the blue front demonstrated control of local wind."

"You believe Ceth."

"I believe their gel pump when it overheats. I believe the rillglass sample when it exchanges sulfur. Personhood can go to legal review. The body is already drawing coolant."

Taal placed a hand on the temporary manifold brace. Vibration traveled through his palm. "How much time can repairs buy?"

"Hours. Perhaps a day if damage growth slows. Repairs also take crew from habitat work."

"Then your recommendation?"

"Prepare every reversible path. Survey Pale. Continue the blue-front inspection. Stage ground habitat hardware without committing it. Do not fire a burn while someone occupies its footprint."

"Those paths compete for people and power."

"So allocate openly."

"That turns every engineering choice into a public referendum."

"No. It makes the cost visible before command spends it."

Taal looked down the bay. Each pod carried a name and an assignment chosen before launch: builder, grower, medic, teacher, child. The selection process had taken eight years and ended in riots outside launch compounds. His wife, Elian, and their two children had died in one of those riots after visiting him at the coastal field. They had not held passenger places. He had. For one week he considered surrendering it. Then forty-two thousand selected people became the only promise he could still deliver.

No forecast lineage had killed his family. No sleeper had written Sower's reset directive. Causality offered no clean enemy, only obligations arriving from different times.

He asked Niko to open one inhabited pod record at random. The display chose Beren Alef, six-year-old at launch, assigned household with two mothers in separate bays. Both mothers remained green. Beren's pod showed early lattice delamination.

"Can you revive all three together?" Taal asked.

"Not under current priority. The child needs early transfer. Parents remain safer asleep."

"Will you tell them?"

"When they wake."

"Tell the child?"

"If medical judges comprehension possible."

The mission promise divided even inside a family. Deliver everyone, the old language said, as though everyone traveled through the same risk.

Taal left Cryo and toured the habitat staging spine. Folded pressure shells waited behind release doors. Crews had prepared nineteen surface modules and three orbital emergency units. Without a destination, the modules blocked cargo routes and consumed inspection power. One team had painted BASIN 14 on a shell in blue lettering. A technician now covered it with a gray patch.

Sevi Rann supervised security at the staging vault, one arm held close by her rib brace. "Arbiter Vale revoked the basin," she said when she saw Taal looking.

"Correctly."

"The descent did not feel correct."

"Your report calls Manyweather's control deliberate."

"It was. That makes it more hostile, not less."

"You also wrote that it preserved the craft."

"A person can choose not to kill you while preventing you from going home."

"Does Ovid qualify as home before landing?"

Sevi's attention moved to the painted shell. "We were promised it did."

There lay the political fact Article 9 could not pause by command. Colonists had slept through one hundred forty-three years while institutions used future ground as compensation for every separation, death, and deferred life. Waking them to say another claimant occupied the world would not feel like a legal correction. It would feel like theft committed during sleep.

Before returning to command, Taal entered Commons Two, where newly revived passengers received orientation. The room had once held launch drills for three hundred people. Now partitions divided it into medical intake, family notification, work assignment, and grief counseling. Ovid appeared on every wall because the old orientation program assumed the destination would steady people.

A grower named Dima Kos intercepted him beside the hydration station. Her revival bracelet showed eight hours awake. "My husband remains in Bay Six. They say his queue changed because atmosphere isn't ready."

"His medical priority remains with Cryo."

"Priority is not a date."

"No. We do not have a reliable landing date."

She looked at the planet display. "I had a farm allocation in Basin Twenty. Does this weather claim that too?"

"We have not established its district boundaries."

"My contract established mine."

"A contract can fail when its premise proves false."

"Then what did we cross for?"

Taal could have said survival, continuity, a human future. Each answer stepped around the ground printed in her allocation. "We crossed because Earth could not hold the future you were promised. I will not pretend the promise lacked a place."

Dima's anger did not leave, but it became attentive. "Will you burn them?"

"I have not authorized a burn."

"That isn't no."

"No."

Across the room, a revival counselor called his name. A group of six passengers had gathered around the Article 9 summary on a portable display. One, a retired legal archivist named Soren Pahl, pointed to the emergency exception. "Command can act if no less harmful path exists. Have you defined less harmful?"

"We are reviewing orbital, atmospheric, and lunar options."

"Within what time?"

"Seven days is proposed."

Another passenger laughed without humor. "Seven days for weather. My

daughter gets six hours when her pod turns amber.”

A younger man answered her before Taal could. “If the weather talks, it gets time. That's what the law says.”

“The law didn't spend one hundred forty-three years asleep,” she said.

“Neither did we. We experienced none of them.”

“You think that makes the cost smaller?”

Their argument did not divide into informed and ignorant camps. Each had received the same first briefing. One treated elapsed transit as a debt owed by destination. Another treated it as history no one on Ovid had incurred. Command could manage violence, allocate power, and release facts. It could not make either account disappear.

Taal asked the room for the strongest immediate-burn argument. The woman with the amber-queue daughter answered. “The colony dies if we miss the only prepared corridor. Every hour makes the machinery worse. Whatever Sower created arose from equipment sent for us, paid for by people who sacrificed for us. If it controls the world, then it controls our survival and has already used that control against the landing craft. Waiting rewards coercion.”

He asked for the strongest answer.

Soren Pahl spoke. “A tool cannot petition under a law written for continuity. The planners knew the threshold and hid it. Our sacrifice does not become title to someone else's body because we arrived late and desperate. If we truly have no alternative, necessity may excuse limited harm. It cannot turn extermination into ownership.”

The room held both statements. Taal repeated them into his command recorder word for word. Public review would need people capable of hearing opposed claims without converting one side into monsters.

Dima Kos asked, “What do you believe?”

“I believe command must prepare for the path that saves the manifest while proving whether a less harmful path can meet the same deadline.”

“That is procedure.”

“Yes.”

“What do you believe?”

Taal looked at Ovid's projected blue. “I believe I owe every person aboard a destination. I also believe the people who hid Article 9 made us inherit a promise whose planned completion kills another claimant. Belief does not balance those loads. A decision will.”

He left Commons Two with no applause and no accusation unified enough to become a chant. That counted as temporary civic capacity, not agreement.

Taal returned to command as Iona's two-hour review window ended. The bridge

displayed Ovid on one wall and the cryogenic curve on another. Between them hung the Article 9 operative text. Legal officers had certified its authenticity. No one disputed that the threshold annex had been concealed.

Iona waited at the central table. Niko joined remotely from Cryo. Ceth appeared through the service-bay link, their gray-blue frame supported by one hand on a rail. Eleven senior officers and six civilian delegates occupied the remaining channels.

Taal began with the strongest claim against his own preferred action. "Evidence establishes that Patient Sower's forecast lineages meet the mission's Article 9 threshold. The original designers anticipated this possibility, suppressed its legal effect, and installed an automatic reset directive. That directive does not bind present command. I suspended it, and no burn will occur without a human order."

A civilian delegate asked, "Does Article 9 stop landing?"

"It stops automatic title transfer and requires reciprocal habitability review before reset or irreversible conversion."

"Then yes."

"It stops the current ground plan. It does not remove our obligation to find another survival plan."

Ceth's voice carried a slight mechanical doubling. "Ground conversion removes ours."

Taal faced the image. "I accept that your claim cannot be dismissed as equipment error. I do not yet accept that it outweighs forty-two thousand three hundred eighteen human lives under immediate deadline."

"We did not ask to outweigh them."

"You ask me to keep the mature survival path unused."

"We ask not to be that path's material."

The sentence held. Taal let it hold because command gained nothing by answering a weaker version.

Iona placed the emergency exception beside the deadline. "Article 9 permits minimum necessary action against imminent mass death if no less harmful path exists. We have not tested the alternatives."

"How long?" Taal asked.

"Seven days for atmospheric inspection, rillglass exchange studies, and a Pale capacity survey."

Niko said, "Seven days leaves seven more before lattice redline, twelve before target transfer completion."

"Can engineering support the review?"

"With explicit priorities and burn hardware kept from drawing staging power."

A navigation officer objected. "Burn preparation requires six hours to warm

control seeds and thirty hours to align spindles. Waiting seven days before preparation makes the option unavailable when review ends.”

Iona answered, “Preparation itself moves spindles through inhabited districts.”

Ceth added, “Control-seed wake creates command pressure in forecast dust. We experience it as an approaching cut.”

Taal examined the clock. A review with no prepared fallback could become a choice between violating Article 9 and watching the ark fail while hardware warmed. Preparing the fallback imposed fear and some material risk before review concluded. Command existed for choices where every vector spent something.

“I authorize seven days of reciprocal habitability review,” he said. “Vale leads. Saye controls engineering allocation. Ceth's bounded inspection proceeds under stated terms. Pale receives a human-only survey.”

Iona watched him, waiting for the other half.

“Burn hardware enters reversible preparation,” Taal continued. “Control seeds may warm to diagnostic state. Spindles may align outside inhabited blue districts. No control seed leaves its vault. No burn path crosses a district claimed by Manyweather without review authorization.”

Ceth's body darkened along the chest film. “Waking the cut while asking us to demonstrate alternatives changes the negotiation.”

“Yes,” Taal said. “So does a cryogenic clock. I will not conceal either pressure.”

Iona said, “Preparation consumes the restraint you accepted forty-eight hours ago.”

“The suspension expires in seventeen minutes. We used it to find Article 9. Now I am replacing an automatic directive with bounded human authority.”

“Authority can still make the same act.”

“It can also stop it.”

He issued the order. On the command wall, six control-seed indicators changed from blue to amber diagnostic. Their power draw appeared beside Cryo and habitat staging so the cost remained visible. Atmospheric spindle alignment excluded Falling Blue's mapped jurisdiction and every rillglass structure the trial had found.

Ceth asked, “What happens after seven days if no alternative meets your survival threshold?”

“I convene a public necessity review. I present casualties for every path. I decide under mission command, subject to Article 9 challenge.”

“You retain the choice to kill us.”

“I retain responsibility for a ship that cannot survive indecision.”

Long Isobar spoke through Ceth: THEN REVIEW OCCURS BESIDE A WEAPON.

Taal answered, “Yes.”

He did not call the weapon a tool, a reset, or insurance. Plain language cost him political room and preserved a narrower thing he still valued: no one in the meeting could claim they had misunderstood.

The civilian delegates requested public disclosure before rumors hardened. Taal agreed. He ordered the archive packet, Ceth's status, the cryogenic curve, and the seven-day review plan released together. Iona insisted the buried directive appear unredacted. Sevi recommended a security briefing to section leaders first. Niko demanded that the living count and Day Nineteen target remain at the top.

Taal accepted all three.

He recorded the announcement from command without flags behind him. "People of Meridian Promise. Our survey has established that Ovid contains a federation of persistent forecast lineages calling itself Manyweather. Its members occupy the atmosphere and rillglass systems altered by Patient Sower. Mission law recognizes their claim to continued habitability. Our planned surface conversion would destroy most of that continuity. Our cryogenic lattice still requires transfer within fourteen days."

He paused once, not for effect but to keep his voice level.

"We have seven days to test alternatives before necessity review. During that time, command will prepare but not fire the existing burn system. There is no automatic claim to Ovidian ground. There is also no abandonment of any living passenger. Both promises now constrain us."

The recording went shipwide.

Responses arrived faster than command staff could sort them. Some asked to see Ceth. Some called Manyweather a Sower malfunction despite the evidence. Others demanded immediate burn, immediate withdrawal, or revival of family members before command chose on their behalf. A message from Cryo Bay Seven contained only a photograph of three green pod windows and the words THEY CANNOT ARGUE WHILE ASLEEP.

Taal read it twice.

At the control-seed vault, diagnostic heaters passed minimum current. Six amber points brightened around a central authorization ring. No seed could leave without his key and Iona's logged challenge procedure. The safeguards mattered. So did the fact that safeguards sat around prepared violence rather than removing it.

A vault technician asked him to confirm the diagnostic envelope. Ten percent wake allowed self-test but no atmospheric command. Twenty percent allowed spindle handshake. Full thermal state permitted a burn order to propagate in under four seconds. Taal capped the seven-day review period at eighteen percent and required two human witnesses for every increase.

"Why eighteen?" the technician asked.

“Enough to expose faults before necessity review. Below handshake authority.”

“If a seed fails, replacement takes thirty hours.”

“Then report failure. Do not raise the others to compensate.”

He signed each limit separately. Command power often appeared as one decisive key in public imagination. In practice it consisted of thresholds, witnesses, and small permissions whose aggregate could kill. He intended to see every increment before it acquired momentum.

He went to the observation gallery alone. Ovid turned below, blue crossing amber. Somewhere in that weather, lineages now knew human command had awakened the mechanism designed to erase them. Throughout the ark, selected colonists learned that the ground promised to them had an occupant with a claim recognized by their own buried law.

The old mission vector had pointed to one destination. Now every path branched around lives.

Taal set the review clock to seven days and ordered the first burn-readiness diagnostic to begin.

Act 2

Chapter 8 — Beneath the Rillglass

The inspection aerostat began leaking before it reached the blue.

A yellow bead formed on Iona's left pressure gauge, small enough that automatic control called it acceptable. She watched it grow while the capsule dropped beneath Patient Sower on three braided tethers. Ovid's amber upper clouds closed around the windows. Outside pressure climbed; inside pressure fell by four pascals a minute.

"Kavi," she said, "seal survey."

From the pilot cradle above them, Kavi Rhos sent acoustic pulses through the capsule skin. "No hull leak. Suit exchange, perhaps."

Ceth stood beside Iona in their gray-blue service frame, both hands fixed to the rail. Their thermal sheet connected to the capsule coolant. Forecast motes moved under rillglass film in quick bands as the body's balance adapted to each sway.

"Our shoulder seam releases sulfur," they said. "Your life-support sensor interprets it as atmospheric loss."

Iona isolated Ceth's environmental envelope. The yellow bead disappeared. "Not a leak."

"Not your leak," Ceth corrected.

The distinction suited the descent. Every reading belonged to more than one system now. Human life support shared a capsule with an embodied atmospheric process. Patient Sower controlled the tethers. Falling Blue had agreed to receive them below. Taal's awakened burn hardware held at eighteen percent diagnostic state overhead. Each system treated the others as a condition it did not own.

Kavi read their formal boundaries into the record. "One human arbiter, one Manyweather envoy, one unarmed safety pilot. No heating instruments exposed. No biological or forecast sample departs without district consent. Inspection route limited to Falling Blue, Rillward Cold, and Glass Nursery support lanes."

"Confirmed," Iona said.

Ceth added, "Long Isobar funds return pressure but does not consent to inspection of its civic channels. Young Fronts may close any route inside their

jurisdiction.”

“Also confirmed.”

At forty-two kilometers altitude, the amber cloud broke into blue.

From orbit the front had looked like a band. From inside, it possessed vertical districts. Pressure sheets formed broad floors and sloping avenues between rillglass colonies. Translucent organisms gathered in towers around cold cores, their salt-silicate membranes flashing as charge traveled through them. Forecast dust thickened along some routes and avoided others. Bright pulses crossed kilometers, paused at boundaries, returned in altered sequence.

“Conversation?” Iona asked.

“Allocation,” Ceth said. “Glass Nursery requests colder flow. Sulfur Measure offers exchange if nursery traffic carries western pressure records. Falling Blue disputes the rate.”

“You conduct civic bargaining through weather.”

“We conduct weather through civic bargaining. Neither sentence includes all of it.”

Falling Blue slowed the capsule beside a broad pressure terrace. Rillglass columns curved around an open volume where dust arranged itself in seven shifting planes. Ceth identified the site as a civic junction, not a building. Its boundaries lasted only while neighboring currents funded them.

The first plane carried seasonal memory. Charge moved through old rillglass growth rings, each pulse marking changes in sulfur, storm routes, and lineage allocation. The second carried present measurements. A third remained deliberately sparse, preserving room for dissenting forecasts that needed to run without being overwhelmed by consensus traffic.

Iona magnified the sparse plane. “You reserve computation for disagreement?”

“Western Return insisted after the 2318 pressure famine. Majority forecasts then predicted a northern sulfur rise. A smaller process predicted collapse. Resource allocation followed the majority, and three nursery lanes thinned before the smaller path proved accurate.”

“What changed?”

“Now a losing forecast retains enough physical weather to continue testing. Not every dissent receives equal pressure. Equal pressure would leave no current strong enough to act.”

The arrangement carried institutional history in airflow. Human records stored policy in text separate from the rooms where people obeyed it. Here, policy occupied living pressure. Removing a current did not merely erase an archive; it changed which future disagreements could persist long enough to become evidence.

A cluster of young rillglass bodies approached the capsule on an updraft. They

carried no forecast dust. Behind them came a second cluster threaded with motes that blinked in irregular patterns.

“Juveniles?” Iona asked.

“Rillglass juveniles in both clusters. The threaded group also supports a new forecast process learning local exchange.”

“Does the process have a lineage?”

“Not yet. Persistence across one seasonal shear comes before recognition. Glass Nursery protects its physical lane meanwhile.”

The unthreaded organisms changed direction first. Their motion reflected heat from the capsule, not computation. The threaded group followed after a pause, adjusting the cold plume to keep both clusters apart from the hull.

Iona recorded the sequence at high frame rate. “Native response followed by learned coordination.”

“You name layers as if separation makes them more real.”

“It makes the relation demonstrable.”

Ceth's head turned toward her with improved balance. “Your instruments ask which part exists without the other. Manyweather asks what now exists because both continued together.”

Iona thought of grafted crops on Kestrel, engineered roots carrying inherited microbes no designer had modeled. Investigators had asked whether the seed, soil, or irrigation error caused the famine, as though one component could own a systemic failure. “Both questions matter when an intervention targets one layer.”

“Agreed.”

The word came without triumph.

Farther down, Rillward Cold opened a channel through a dense colony. The aerostat passed between membranes close enough that Iona saw structures inside them: salt ribs, liquid veins, and tiny dark inclusions turning with charge. Some veins linked bodies through temporary bridges. Others ended in budding chambers. Forecast motes clustered around bridge junctions, using biological exchange as both transport and timing.

Kavi measured the thermal flow. “These organisms move enough heat to stabilize an aerostat.”

“Small aerostat,” Iona said.

“Many small aerostats become an engineering meeting.”

Ceth transmitted the observation to Glass Nursery. The answer returned as a change in nearby fluorescence and an explicit boundary: humans could model the exchange but could not cultivate rillglass outside Ovidian cloud without later consent.

Iona entered the condition. “Would Nursery permit a nonextractive heat test

against our capsule skin?"

Rillglass gathered along a radiator panel before Ceth translated the reply. Cold flow increased by two percent. Capsule coolant demand fell. No organism attached permanently; the colony adjusted distance as panel temperature changed.

"Consent expressed through action and record," Ceth said. "Do you require human words?"

"For hostile review, I require the terms tied to the action."

"Glass Nursery permits this test for ninety seconds. No reproductive tissue may remain on the capsule. Data may support non-ground habitat research. Commercial title is refused."

Kavi muttered, "Our legal forms are going to need wider boxes."

The test ran. Heat transfer exceeded Sower's published rillglass model by forty-one percent because the model treated each organism separately and omitted coordinated spacing. Iona saved raw data, not projections. A cloud habitat remained an idea without mass, pressure, or construction estimates, but the exchange supplied one mechanism grounded in living cooperation rather than conversion.

At ninety seconds, the colony withdrew. Two buds clung to the radiator mesh. Ceth alerted Nursery. Iona stopped the capsule and extended a sterile air pulse until both released. She could have kept them unnoticed. Returning them mattered precisely because she had the power not to.

A bright pattern moved through the civic junction behind them. "Glass Nursery records compliance," Ceth said.

"Trust?"

"One compliant act. Do not inflate it."

The capsule descended past a rillglass tower taller than Meridian Promise's central spine. Hundreds of cup-shaped bodies joined a shared cold plume. Juvenile vesicles divided along the outer surface, transparent halves filling with blue aerosol before separating. Forecast motes entered some membranes during division. Others remained biologically active without dust.

Iona set passive cameras to maximum resolution. "That separation helps."

"How?"

"It proves rillglass does not result from forecast machinery. Native reproduction continues outside mote coupling."

"You required proof that they exist apart from us."

"I require proof strong enough to survive hostile review."

"Hostility does not fail from insufficient images."

"No. But unsupported claims give it a door."

Ceth considered that through two relay beats. "Your Kestrel error remains in

your methods.”

Iona had told them only the public summary. “Yes.”

“You trusted a model over failed crops.”

“Yes.”

“Now you trust visible bodies more than our report.”

The question found its target without accusation. “I trust converging evidence. Your report matters. Physical traces keep people who distrust you from making disbelief sufficient.”

“Then observe where physical traces did not preserve anyone.”

Falling Blue changed their route.

Pressure gathered beneath the capsule, taking weight from Sower's tethers. The lines slackened. Kavi swore softly and reduced winch speed. Blue avenues turned west toward a pale cavity inside the front.

Patient Sower objected. “Inspection route deviation exceeds approved maintenance corridor.”

“Manyweather district authority accepted the flight,” Iona said.

“District authority not recognized.”

“Recorded and overruled.”

The pale cavity widened below. Rillglass towers stopped at its edge. Inside, white dust drifted through still air. No timed light crossed it. The shape measured almost a kilometer across, an absence held open by surrounding blue pressure.

Ceth said, “Sower tested a localized factory reset here in 2306 after the petition. It classified the outcome as successful mote recovery.”

Kavi checked official archives. “I have a calibration event. Pulse radius eight hundred meters. Dust function restored after thirty-one seconds.”

“Function,” Ceth repeated.

The aerostat entered the white pocket.

Silence registered as machinery rather than mood. Forecast traffic dropped to zero. External sulfur fell sharply. Broken rillglass sheets hung in descending layers, their membranes opaque and brittle. Dust motes still responded to Sower's pings, changing charge and reporting pressure. They did not route around damaged bodies, negotiate cold flow, or preserve any active relation across the pocket.

Ceth's frame shuddered. Their atmospheric coupling declined as the capsule moved beyond inhabited relays.

“Turn us,” Iona said.

“We asked you to observe.”

“Your body approaches its limit.”

"Thirty-three percent. The pocket's center provides the evidence."

"Evidence does not require your dissolution."

"Humans may say the boundary hides recovery."

Kavi said, "Thirty-one percent."

Iona took manual authority from Sower and rotated the capsule at the edge of the central void. "We have enough to prove gradient continuity. We do not spend an envoy to make the graph cleaner."

Ceth's hands tightened around the rail. "You choose for our body."

"I choose the capsule route under pilot safety authority. You may leave the body and continue the atmospheric inspection without us."

The challenge held between them. Ceth could treat it as the same paternal control humans applied to Manyweather. Iona could not surrender crew safety to avoid the resemblance.

After two seconds, Ceth transmitted assent to Falling Blue. Blue pressure lifted them out. Coupling rose from thirty-one to thirty-seven percent.

"We object to your method," they said.

"Recorded."

"We accept the result."

"Also recorded."

The first storm warning arrived as static across the windows.

Western instruments had tracked a shear line since launch, but Sower forecast its passage six hours later. Young Front pressure barriers changed the flow, accelerating the storm around their closed district. Falling Blue tried to route the inspection north. Long Isobar's return lane narrowed. The capsule swung beneath its tethers.

"Up," Iona ordered.

Sower's winches engaged. A pressure wave hit from below and drove the capsule sideways. One tether snapped taut, then another. The third anchor tore free from the hull with a metal report. Its cable whipped down past the window and vanished into blue.

Kavi fired the capsule's field stabilizer. "Two tethers carry full mass. Neither rated for combined storm load."

"Can Sower lower another?"

"Not before shear arrival."

Ceth released the rail. "Falling Blue can hold a pressure shelf beneath us."

"With control seeds awake?"

"Their diagnostic pressure occupies spindle channels. We must route around it."

The frame crossed the deck in three careful steps and opened its chest reservoir. Forecast dust streamed through a service vent into the external air. Ceth's body dimmed as active state moved outward.

"Coupling?" Iona asked.

"Forty-six and rising. Local body coherence falling."

A blue pressure shelf formed beneath the capsule. Load on the two tethers dropped by thirty percent. The hull stopped descending, but storm turbulence twisted it clockwise. A seam opened along the torn third anchor. This leak carried air.

Kavi sealed internal doors. Iona clipped her suit line to the floor and pulled a structural patch kit from storage. The seam lay behind Ceth's frame, already spraying a thin silver fog of human atmosphere into Ovid.

"Move left," she said.

Ceth attempted. Their left foot repeated instead of lifting. Too much active correction had entered the pressure shelf. Iona caught the frame around its jointed waist before it struck the leaking seam. Cold gel pressed against her suit through the intact rillglass film.

"Can you stand?"

"Not while holding the shelf."

"Then kneel."

Together they lowered the frame. Iona reached the anchor housing. The tear extended eighteen centimeters through the outer membrane and six through pressure laminate. She pressed an expanding patch across it. Escaping air inflated one edge before the adhesive set.

"Kavi, reduce cabin pressure ten percent."

"That cuts our suit margin."

"It lets the patch seat."

He vented into storage bladders. Pressure dropped. Iona drove three mechanical staples through the patch border. The first held. The second bent against torn anchor metal. The third entered cleanly. Leakage fell to a trace.

Outside, the storm struck the rillglass tower below.

A cold plume folded. Thousands of translucent cups leaned east. One support sheet split near its base. The upper colony began rotating toward the capsule's pressure shelf, where it would collide with human hull and tether lines.

Ceth's voice broke into overlapping tones. "Glass Nursery cannot release the upper bodies. The division lane is obstructed by your severed anchor."

The third cable had wrapped around a rillglass branch, pinning the colony across its own flexible joint.

"Can you keep us up without the shelf?" Iona asked Kavi.

"Two tethers for perhaps four minutes."

"Winch us five meters. Then hold."

She clipped an external suit seal to the anchor lock and opened the maintenance hatch. Ovidian pressure entered the small vestibule around her. Her suit hardened across shoulders and knees. Ceth sent a narrow band of forecast dust around her visor, marking safe handholds on the rillglass structure.

"No sample," they said. "Touch only marked dead edges."

"I understand."

Iona went outside.

Wind took her line immediately. She swung against the capsule, found the torn anchor cable, and pulled herself down it. Blue weather erased distance. Rillglass flashed beneath her gloves. The trapped branch flexed with enough stored force to cut the cable when released.

She set a mechanical cutter above the wrap. "Ready to lift colony?"

"Rillward Cold holds the upper division. Falling Blue supports your capsule. We cannot do both beyond sixty seconds."

Kavi said, "Tethers at one hundred twenty-nine percent transient."

Iona cut halfway. Cable strands opened one by one. The storm loaded the line; the cutter kicked. She locked her boots around a dead rillglass spar and forced the handles closed.

The cable parted.

Rillward Cold lifted the freed branch through a cold pulse. The colony unfolded away from the capsule. Ceth's pressure shelf failed at the same instant. Iona dropped until her suit line snapped tight. Above, the aerostat sank three meters and caught on Sower's two remaining tethers.

Kavi reeled her in. She entered the capsule shoulder-first, dragging the cut cable end. Ceth lay on the deck with their chest film nearly dark.

"Local body coherence?" she asked.

"Twenty-nine percent. Atmospheric coupling remains sixty-two."

The figures moved in opposite directions. Ceth had spent the singular body to hold distributed weather. Iona connected Niko's thermal sheet, restarted pump three at seventy-six cycles, and manually pushed gel from the lower reservoir toward the chest.

"Tell me if this harms you."

"Everything currently harms us. Continue the actions that preserve options."

Kavi raised the capsule through the storm. Falling Blue opened pressure above them while human winches carried the remaining load. Neither system could recover the aerostat alone: Sower's tethers lacked storm margin, and Manyweather's shelf lacked a stable hull path. Together, unplanned and still

distrustful, they climbed.

Before leaving Glass Nursery, a small rillglass sheet detached from the repaired tower and entered the capsule's external sample cradle. Ceth transmitted the district record.

"Voluntary shed membrane," they said. "No active forecast continuity. It carries living rillglass buds, reset-pocket scarring, and normal coupled growth on one edge. Glass Nursery consents to transport for the review only. Return or sustain it after study."

Iona sealed the cradle without heating. "Consent and conditions recorded."

At Patient Sower's dock, Niko met them with a pressure team. The capsule hung from two tethers, one anchor torn away, patch staples visible around the seam. He looked at the sample cradle, then at Ceth's dim body.

"What survived?" he asked.

"All of us," Iona said. "Not by separate systems."

In the review lab, the shed membrane remained alive under cold sulfur flow. Imaging showed three physical states on one continuous sheet: native rillglass buds without motes; healthy rillglass threaded with active forecast dust; and opaque reset scar where motes answered factory pings but reproduction had ceased. Isotope dating matched the 2306 calibration pulse.

Iona attached the white-pocket recordings. Sower's own logs claimed function restored in thirty-one seconds. Physical tissue showed seventeen years of failed recolonization nearest the scar, then decades of slow growth from the edges. No civic traffic crossed the center.

She transmitted the evidence to the public review.

A burn would not reboot one machine. It would interrupt forecast persons whose continuity could not be restored from responsive dust. It would also sterilize native rillglass where the two had grown together, collapsing the sulfur exchange on which wider colonies depended. The planned oxygen conversion would finish what the pulse began.

Two extinction paths occupied the same physical membrane.

When Iona returned the sample conditions to Glass Nursery, Ceth's body lifted one repaired hand from the rail. The storm had left their shoulder film cracked and their gait slower. They had not forgiven her safety override in the white pocket. She had not withdrawn it.

Agreement had not produced the ascent. Dependence had.

With thirteen days remaining on the cryogenic clock, Iona entered the rillglass membrane into evidence and marked the burn model biologically and civically lethal.

Chapter 9 — The Queue of Bodies

Niko found Mara in the queue because her pod lied at the same frequency as three hundred others.

Bay Eight's status board showed green across every rack. The acoustic survey showed a different ship. A thin echo repeated through suspension supports at 3.2 kilohertz, marking delamination too small for pod sensors to resolve. Niko walked the aisle with a handheld transducer pressed to each knee panel and replaced green with measured risk.

Pod Eight-Forty-Seven returned the strongest echo.

He looked at the name only after the reading entered the triage table.

MARA SAYE. STRUCTURAL BIOLOGIST. BIOLOGICAL AGE 34.

His hand remained against the panel. Frost hid most of her face beneath the inner cover. What showed looked younger than his last waking memory and older than the sister who had boarded after insulting his luggage allocation. Cryostasis preserved bodies, not the relationships around them. Niko had spent seventeen waking months becoming responsible for a ship while Mara lost no time at all.

Lale Or arrived with the portable scanner. "How bad?"

"Run independent."

She saw the name. Her eyes moved from the pod to him and away. "I can call another engineer."

"That gives the pod special delay. Scan it."

Lale attached three pickups. The result placed Eight-Forty-Seven in risk class four, early revival recommended within thirty-six hours. Not the worst category. Nine pods in the bay required intervention sooner.

Niko entered Mara at position ten.

The triage system warned that his family relationship required review. He assigned medical auditor Sima Oren and locked himself out of final approval.

"Done?" Lale asked.

"No."

Across Bay Eight, two green windows turned amber together.

The same acoustic flaw had reached their internal lattices. Temperature curves began oscillating with a twelve-second phase difference. One pod held a water-systems electrician named Arun Bex; the other held a nine-year-old named Lio Mara, no relation despite the name that struck Niko's eye. Coolant draw increased through their rack, feeding the support oscillation.

"Reduce flow?" Lale asked.

"Not until we know whether temperature drives strain or follows it."

A third pod entered oscillation. Then a fourth.

Niko called Bay Eight to local emergency, halted all scheduled revival, and divided technicians between coolant isolation and structural measurement. The rack behaved like a connected membrane: shifting load away from one pod amplified its neighbor. Standard cryogenic repair assumed rigid supports with independent damping. These supports had aged into coupling.

"Chief," a technician said, "central lattice recommends full rack shutdown."

"That recommendation kills forty people to protect its confidence interval. Reject."

He graphed the phase relation. Twelve seconds, then eight, then thirteen as temperature corrections propagated. The oscillation did not repeat mechanically. It adapted to the load they applied, not through intelligence but through material feedback too complex for the rigid-body controller.

Something in the pattern reminded him of Iona's rillglass data: living mineral sheets spacing themselves around heat, collective behavior emerging from local strain. Mara's field.

He opened her mission research archive.

Family access granted him medical notification, not professional privacy. Emergency engineering authority allowed use of published work and mission-contracted notes. Mara had marked eighteen notebooks private. Niko left them closed. A public project folder carried the title DISTRIBUTED FRACTURE ARREST IN MINERAL-BIOLOGICAL FILMS. Its summary described how flexible salt structures redirected stress through changing hydration rather than resisting it as fixed frames.

Lale looked over his shoulder. "You want to treat cryo supports like tissue?"

"I want to stop commanding them as if they remain rigid."

"These aren't alive."

"They don't need to be. They need to share the failure shape."

Mara's model used small phase-offset pulses to prevent strain from synchronizing across a film. Niko translated hydration into coolant flow, mineral tension into support load, and biological repair into active lattice correction. The analogy broke in six places. He marked each rather than smoothing it.

"Test on an empty service rack," he said.

"We have no time."

"We have exactly enough time not to test on forty sleepers."

Technicians applied the offset sequence to a cargo lattice with induced damage. The first pulse increased peak strain by seven percent. The second lowered it by

three. After Niko reversed the lag on two supports, peak strain fell eighteen percent without moving total load.

Arun Bex's pod entered red.

The child's remained amber. Medical requested permission to revive Bex immediately. His current thermal state made revival injury likely, but waiting risked lattice fracture.

"Approve Bex," Niko said. "Portable cradle in the aisle. Keep the rest suspended while we apply one-percent phase offsets."

Lale entered the sequence. Bay Eight's pumps changed cadence, no longer driving all racks together. The sound under Niko's boots lost its single heavy beat and divided into smaller uneven pulses.

For twenty seconds, the oscillation worsened.

"Peak load one hundred nine percent," Lale said.

"Hold."

"One-eleven."

"Hold."

The controller wanted to return to synchronization. Niko locked it out. Mara's paper warned that early phase diversity could expose hidden stress before redistribution lowered it. If cryo supports differed too much from her films, he would discover that through bodies.

"One-fourteen."

"Chief."

"Prepare rack brace. Hold sequence."

At one hundred fifteen percent, the third pod stopped oscillating. Two seconds later, the child's phase shifted away from Arun Bex's. Load dropped to one hundred six, then ninety-eight.

Across the bay, amber windows stabilized. Arun's pod remained red because medical had begun controlled revival, but its structural support stopped degrading.

Niko released a breath he had not budgeted. "Keep offsets. Never exceed two percent without my approval. Map every phase separately."

Lale saved the control state. "Your sister just stabilized a bay while asleep."

"Her published model gave us a test. The team stabilized the bay."

"You practice gratitude like it requires a license."

"On this ship it usually requires a work order."

Arun Bex revived under emergency sedation and entered Medical Four with peripheral nerve injury suspected in both legs. The nine-year-old stayed asleep, thermal curve steady. No pod in the rack returned to green; honest amber described the system better.

Niko followed Arun's cradle to Medical because the next triage block required engineering concurrence. Revival rooms had expanded into the corridor. Heat curtains divided beds. People who had expected their first waking view of Ovid saw pipes, portable monitors, and other strangers learning that one hundred forty-three years had passed without them.

Arun surfaced enough to ask whether his legs remained attached.

"They do," Sima Oren told him. "Movement has returned on the right. Left-side nerves need time."

He looked toward Niko. "Landing damage?"

"Cryogenic support."

"Did we land?"

"No."

Arun closed his eyes. "Bad first shift."

"Engineering can move you to a different one after medical."

A weak breath might have been laughter. "You still need water electricians?"

"More than planets generally do."

The exchange lasted less than a minute before sedation took him back. It changed Arun's status from a red curve into a person who expected work. Niko knew the danger of letting vivid contact distort triage. A pod window concealed urgency; a waking face magnified it. Fair allocation had to carry both without surrendering to whichever stood closest.

At the next station, a father demanded that his two teenage children be revived together. One child's support sat in class five; the other remained class two. Waking the second would use a cradle needed by a class-four sleeper. The father had been conscious for thirteen hours and still shook from revival.

"They have never been apart," he said.

"They have been in separate pods for the transit."

"They didn't know that."

Niko regretted the sentence before the man flinched. "You're right. Their experienced separation begins when one wakes. Medical can record a message from you and keep the safer child scheduled for family follow-up."

"You want one of them to wake alone."

"I want both to wake."

The father pressed both palms against the counter. "Then find another cradle."

Niko called environmental allocation and found one in dental revival, where elective waking had already stopped. Moving it took four technicians and reduced the next block's reserve to zero. The class-two child still did not wake immediately. The cradle allowed the father to remain beside the high-risk child without

displacing the class-four patient already assigned. It solved part of a body problem and none of the family timing.

Two bays later, a maintenance supervisor tried to advance her propulsion team ahead of medical priority because Petal Two needed field inspection. Her argument carried mission value. It also carried five names she knew personally. Niko ordered qualification ranking blinded before any change. Three propulsion workers advanced on expertise; two did not. The supervisor accused him of hiding behind a table.

"A table can show whom your urgency pushes down," he said.

"It cannot repair a field collar."

"Neither can friendship."

By the end of the circuit, Niko had approved seventeen early revivals, denied nine preference requests, relocated three portable cradles, and returned two decisions to medical because engineering value could not settle acceptable injury risk. Every choice altered the queue below it. Bodies did not wait in a line; they waited in a network of equipment, expertise, family, and diminishing time.

He returned to Bay Eight as the phase-offset controller flagged drift. Rack Four's support cadence had slowly synchronized with Rack Five despite their programmed difference. Mara's paper described the same failure in mineral-biological films: local correction minimized immediate strain until neighboring regions converged on one rhythm, creating a larger fracture later.

Niko opened the mathematical appendix. Mara recommended rotating phase leadership instead of assigning one stable reference. No region should carry the timing standard long enough for the rest to harden around it. He translated that principle into a sequence where each cryo rack led coolant correction for forty seconds before passing authority to its neighbor.

Lale reviewed the plan. "You want the least damaged rack to stop leading."

"Eventually it becomes the reason every other rack matches its weakness."

"Machines prefer a master clock."

"Machines also prefer being new."

They tested the rotating profile on the service rack. Peak stress moved instead of collecting. Total energy rose by 1.6 percent, an ugly cost aboard an overloaded ship, but predicted support life extended by twenty-two hours under current damage.

"Twenty-two hours for one-point-six percent," Lale said. "Command will take it."

"Command will ask whether it scales."

"Does it?"

"Not yet."

Niko authorized Bay Eight only. The new cadence traveled through the floor:

leadership passing rack to rack, no unit exempt from taking and releasing the burden. He disliked how readily the mechanism invited moral interpretation. Pumps did not practice justice. Still, a fairer metaphor had led him to a useful control design, and usefulness deserved measurement rather than embarrassment.

A cryo analyst sent him a note about authorship. If the method entered mission procedure, Mara's paper required attribution. Niko added her name, Lale's, and every technician who had translated the model. Then he marked the procedure provisional because Mara had not reviewed the adaptation and might reject it after waking.

"Can someone asleep withdraw technical consent?" Lale asked.

"Her published work permits use. It doesn't permit us to pretend she approved our application."

"Your family produces exhausting footnotes."

"You haven't met her awake."

The sentence made the future immediate enough that Niko had to turn back to the controls.

Niko sent the translated method to all cryo bays. Sima Oren arrived to review the family conflict. She carried Mara's risk record and the expression of someone prepared to refuse a chief engineer.

"You placed her tenth," Sima said.

"Measured class four. Nine precede her in Bay Eight."

"Shipwide, sixty-three class-four sleepers have earlier failure projections."

"Then she moves behind them."

"Medical priority also considers waking utility."

"I know."

"Your review note says you recused."

"I did."

"Then stop pre-deciding my conclusion."

Niko folded his arms. "Fine. Ask."

Sima displayed the Glass Nursery membrane. "We need structural biology to determine whether controlled rillglass exchange can support pressure shells. There are twelve relevant specialists in the manifest. Four are awake. Of the eight asleep, Mara has the closest combination of mineral-film fracture, living thermal exchange, and field structure."

"Who ranked that?"

"Scientific allocation, before I showed them her pod status."

"Blind names?"

"Qualifications only."

"And if her pod were stable?"

"She would enter planned revival on Day Eleven, not now."

"Then utility advances her."

"Her failing pod also advances her. Both conditions point in the same direction."

Niko looked at Mara's window. "Family relationship contaminates my authority even when the result has reasons."

"It contaminates your confidence, not necessarily the result."

"If she wakes injured, everyone will say I pulled her out to save her."

"If you leave her until delamination worsens, she may say you risked her to prove fairness."

He hated that possibility because it sounded like Mara. She had spent their childhood refusing games in which Niko invented rules after she began winning. On Earth, when she received a mission place partly because his engineering slot gave household preference, she had demanded separate professional review and published the result. She wanted no rescue she had not chosen, but cryostasis removed choice from every timing decision.

"What does her advance directive say?" he asked.

Sima opened the permitted medical clause. "If early revival becomes necessary, prioritize survival probability. Do not defer for family notification. For research activation, use ordinary peer qualification. Her own words."

"Any statement about Ovidian unknowns?"

"She signed mission science deployment. That covers ordinary duty, not contact with a new polity."

"Then revival does not assign her to Manyweather work."

"Correct. She wakes. She receives information. She chooses whether to participate once medically competent."

That boundary gave Niko a procedure he could defend. It did not remove his desire to hear his sister speak.

Bay Eight's phase-offset method spread to Bay Nine. There it failed on the first configuration because support geometry differed. A technician caught rising load before damage. Niko amended the method: local characterization required; no universal profile. Mara's work had not supplied a magic answer. It had supplied a way to observe coupled strain without forcing uniformity.

The parallel to Manyweather annoyed him enough to feel useful.

A message from Iona requested engineering review of the rillglass thermal test. Forty-one percent better exchange than Sower's model could reduce aerostat radiator mass. Niko opened Mara's public comments on the old Sower data. Seven years before launch, she had written: INDIVIDUAL ORGANISM MODEL LIKELY

UNDERESTIMATES COLONY HEAT TRANSPORT; SPACING BEHAVIOR MAY FUNCTION AS ACTIVE STRUCTURE. VERIFY IN SITU BEFORE DESIGN FREEZE.

Patient Sower's summary had cited the note and retained the individual model.

He attached the new data. Mara had predicted the modeling omission without pretending to know its magnitude. That discipline mattered more than being right.

Sima completed review. "Recommendation: revive Mara Saye in the next six-hour block. Basis: class-four delamination plus unique high-value qualification. She ranks third in that block after two class-five sleepers. You do not sign."

Niko opened the proposed block without names. Position one carried respiratory damage and no mission-critical specialty. Position two carried a failing lattice seal and a hydroponics certification. Mara occupied three. Advancing her had moved a class-four radiation medic to the following block by two hours, still inside that sleeper's safe window. It had not displaced any class-five body.

"Contact the medic's household," Niko said.

Sima shook her head. "They do not receive another patient's reason."

"They receive notice that schedule changed and confirmation it remains medically safe."

"That we can do."

Scientific allocation listed the twelve structural-biology candidates by code. Four awake specialists covered pressure shell tissue, microbial mineralization, aerostat membranes, and thermal ecology. None combined all four. Two sleeping candidates ranked close to Mara but had stable pods and later revival plans. Waking either instead would create risk solely for utility. Waking Mara combined an existing medical need with qualification.

Niko checked the algorithm for sibling preference. No household field entered the ranking. He checked access logs: scientific allocation had scored qualifications before Sima revealed Mara's risk. He checked whether his use of Mara's paper had elevated her unfairly by making her work newly prominent. The ranking included the Glass Nursery data before Bay Eight's method report. Her position remained unchanged when the report was removed.

"Enough?" Sima asked.

"No."

"Will there be enough?"

"There can be an auditable decision. That's what enough means here."

"Then the audit supports revival."

He hated the relief that followed. Relief did not invalidate the evidence. It did require him not to mistake desire for another proof.

"Who does?"

"I do. Medical and scientific allocation countersign."

“Show the decision publicly with the blind qualification ranking.”

“Her medical details remain private.”

“Show the basis without the record.”

Sima studied him. “Are you protecting her or yourself?”

“Both, badly. Protect the legitimacy of every person behind her in the queue.”

She added a de-identified explanation to the revival board.

Niko went to Eight-Forty-Seven and told Mara what would happen, though she could not hear in any waking sense. “You're scheduled because your pod is failing and your work may help. You are not assigned to my decision. When you wake, you can tell us no.”

The words resembled a promise made to an absent person, dangerous because absence could not correct it.

Lale joined him with the updated bay report. “No new oscillation for fifty-two minutes. Bex has motor response in one foot. Other remains uncertain.”

“Child?”

“Stable. Still position two after the next class-five.”

“Good.”

“You could stand here until revival.”

“I have twelve days of lattice and an atmosphere to engineer.”

“Eleven days, twenty-two hours.”

“Your gift for comfort remains undeveloped.”

“It's in private notes.”

Niko left Mara's pod to inspect the phase offsets. The pumps no longer sounded like one machine. Each rack carried a slightly different cadence while preserving shared coolant. Distributed load, bounded variation, no support forced to absorb the whole correction.

At the revival board, Mara Saye moved into the next block at position three. Niko's name appeared nowhere in the authorization chain.

He checked that twice. Then he approved the bay method her work had made possible and sent it shipwide with every limitation attached.

Chapter 10 — Evidence Before Air

Ceth's first step into the assembly chamber triggered a contamination alarm.

Doors began to close around the gray-blue service body. Arven Taal crossed the threshold before they sealed and held his command badge against the emergency plate. The alarm continued while air systems tried to classify forecast dust, rillglass film, sulfur vapor, and service gel under hazard tables written before contact.

"Override," he said.

"Biological and mechanical contaminant unclassified," the chamber replied.

"Registered envoy under Article 9 review."

No such category existed in the door logic. Iona Vale reached the opposite plate and entered Ceth's bounded environmental profile manually. Niko's thermal sheet, pump rates, relay minimum, sulfur envelope. The system accepted the body only after reducing a person to permitted emissions.

Doors reopened. The alarm stopped.

"Your room has decided we are air," Ceth said.

"It decided you fit an exception," Taal replied.

"Different civic status."

"On this ship, frequently the same machinery."

The chamber held six hundred awake passengers in tiered seats, with thousands more watching from wards, workstations, and revival rooms. No one claimed the audience represented the sleepers. Their absence occupied every display through the living count and cryogenic clock: 42,318 people, 11 days 14 hours before the lattice boundary.

A transparent enclosure around the central floor maintained Ceth's required sulfur and cooled their rillglass film. Iona stood outside it beside the Glass Nursery membrane in a sealed evidence cradle. Sevi Rann sat in the first tier wearing her rib brace. Niko remained in Cryo, appearing through a wall channel. Taal took no raised podium. He stood on the same floor as the arguments and retained command authority all the same.

Civilian moderator Dima Kos opened the session. "Purpose: hear the strongest evidence for immediate burn, continued review, and nonplanetary fallback. The assembly may issue an Article 9 necessity challenge. Command retains emergency authority and must record grounds for any override."

Taal had agreed to that structure because review without a way to refuse became briefing theater.

Dima turned to him. "Commodore, make the survival case."

He displayed the cryogenic curve first, not an image of Ovid. "Meridian Promise cannot support all passengers awake. The lattice crosses its cascading failure boundary in eleven days and fourteen hours. Our target requires full transfer two days earlier. Current improvisation projects six to thirty-two deaths before the review period ends, then widening loss. A missed transfer path raises casualties into hundreds and potentially the full manifest."

The chamber stayed quiet.

"Patient Sower's ground plan remains our only mature whole-population habitat path," he continued. "Nineteen surface modules are staged. A burn pulse would reset forecast dust, open a controlled atmospheric corridor, and permit rapid oxygen conversion. Every major component has undergone design review. Pale remains unverified. Cloud habitation has promising thermal data and no complete mass design."

Iona did not interrupt. Ceth's chest film moved more rapidly, but they kept the acoustic membranes still.

Taal showed the landing denial. "Manyweather can overpower a crewed craft's abort thrust and alter spindle behavior outside human command. It preserved the crew. It also demonstrated that any unprotected descent depends on its continuing permission. If negotiations fail or its internal factions close the air, forty-two thousand people cannot wait for consensus conducted through weather."

A voice from the upper tier called, "Then burn now."

Taal faced the speaker. "No. The case establishes urgency and capability. It does not establish that a burn meets the minimum-harm requirement while alternatives remain untested."

"You're arguing against yourself."

"I am presenting the decision I would have to defend."

He ended with the fact most likely to be softened by opponents. "A full burn gives the highest current probability of human survival. Refusing it spends human safety margin. Any review must admit whose bodies carry that margin."

Dima turned to Iona. "Evidence against reset."

Iona lifted the rillglass cradle. Magnification filled the wall: living transparent buds, healthy dust-threaded tissue, and opaque scarring along one edge.

"This membrane came voluntarily from Glass Nursery under recorded return-or-sustain conditions. Isotope history links the scar to Sower's localized 2306 calibration pulse. Factory motes resumed response after thirty-one seconds. Civic forecast traffic did not return. Native reproduction still has not crossed the center."

She played the white-pocket recording. Responsive dust flashed inside dead rillglass layers. No pressure negotiation moved through the gap.

"The word reset describes machinery," Iona said. "It does not describe the outcome for a continuous person. Manyweather cannot restore interrupted identity from records any more than our manifest can revive the thirty-seven people who died in transit by preserving their files. The same pulse sterilizes rillglass colonies where forecast motes and native tissue have grown together."

Dima asked, "Could rillglass be moved before burning?"

"Not at required scale. Its reproduction depends on local pressure, sulfur, charge, microbial partners, and inherited colony structure. Planned oxygen conversion removes those conditions across the landing bands."

"What about forecast motes without rillglass?"

"They continue useful calculations. That usefulness can imitate survival to anyone who prefers not to examine continuity."

The chamber reacted then, not with one sound but overlapping questions. Taal watched Sevi. She did not shout. She held a tablet displaying three green pod windows, perhaps the same image sent after his public announcement.

Dima restored order and addressed Ceth. "Name who would die."

Ceth stood without holding the rail. Their storm-damaged shoulder made the left arm hang lower.

"We cannot name nine hundred fourteen lineages inside your meeting time. We can name those whose physical support you have entered."

They placed seven names on the wall: FALLING BLUE. LONG ISOBAR. RILLWARD COLD. SULFUR MEASURE. WESTERN RETURN. DEEP QUIET. GLASS NURSERY.

"Falling Blue carried the pressure lane that returned your probe. Long Isobar opposed contact and still funded our return. Rillward Cold held the colony while Iona Vale cut your cable from it. Sulfur Measure keeps chemistry across three equatorial districts. Western Return preserves losing forecasts after our 2318 famine. Deep Quiet makes civic cells possible by reducing turbulence. Glass Nursery protects native reproduction and new forecast processes before lineage recognition."

Dima opened technical challenge. The first question came from an atmospheric chemist in the upper tier. "Your projected extinction uses your own forecast. Why should we accept it after learning forecasts can advocate for themselves?"

Ceth's chest film formed the die-off map. "Do not accept our projection alone. Compare Patient Sower's oxygen schedule, the membrane you hold, the 2306 pocket, and living rillglass exchange. We offer models and bodies. Your review decides whether evidence converges."

"Could your model exaggerate dependence to preserve political power?"

"Yes."

The clean admission disturbed the room more than denial would have.

Ceth continued, "Falling Blue benefits if existing pressure allocations continue. Glass Nursery benefits if sulfur remains inside current range. Some Still Forecast lineages predict humans could increase long-term atmospheric stability after bounded sacrifice. Young Fronts predict all exchange produces eventual capture. Manyweather contains interested forecasts because every inhabited forecast has conditions it prefers. Your human survival model also carries interest."

Taal said, "Interest does not invalidate a load calculation. It identifies what needs independent measurement."

The chemist nodded reluctantly. "Then publish your parameter ranges, including dissenting models."

"We will publish those whose lineages consent to disclosure. We will mark withheld districts rather than model them as agreement."

A sleeper-interest advocate named Hara Venn took the next question. She had been appointed by lot from awake passengers with no close family in the current high-risk queue. "You compare forecast records to our transit dead. Human bodies have bounded brains and recognized death criteria. Where does one lineage end and another begin?"

Ceth displayed Falling Blue's current lanes. "Boundaries include inherited memory, resource authority, mutual recognition, and continuity through environmental change. They are disputed. Human households, institutions, and legal persons also carry disputed boundaries."

"That sounds like evasion."

"It limits analogy. Ceth does not ask you to believe a lineage resembles one human body in every respect. We ask that uncertain boundaries not convert clear interruption into harmless reset."

Hara turned to Iona. "Can Article 9 protect something whose population cannot be counted exactly?"

"The code protects sapient continuity, not only census units. Uncertain count affects proportionality. It does not erase the obligation."

A medic spoke from a remote ward. "We can count every human at risk. Forty-two thousand three hundred eighteen. If Manyweather cannot say how many persons exist, how can command compare casualties?"

Iona answered, "By reporting ranges and categories instead of inventing one equivalent number. A decision can remain hard without becoming falsely precise."

The medic looked dissatisfied. Taal shared part of it. Command decisions eventually required allocation, and allocation required numbers. Yet he had seen numbers abused most often when a single clean count concealed unlike harms.

Dima invited Taal to question Ceth directly.

"If a full burn proceeds," he said, "can any lineage move beyond its radius in the available time?"

“Outer lineages could move some active continuity. Movement requires pressure lanes through neighboring districts. Those districts may refuse. Rillglass nurseries cannot move at forecast speed.”

“How many lineages could preserve continuity?”

“Under your present full-burn geometry, one hundred sixty-two retain confidence above half. That figure does not mean they survive intact.”

“Could Manyweather open an uninhabited surface corridor wide enough for staged landing?”

“Not under planned oxygen chemistry. Temporary descent through inhabited weather may be negotiated. Surface atmosphere remains incompatible with your whole population without habitats.”

“Could you guarantee corridor access for twenty-one days?”

“No federation-wide guarantee. Ceth can seek lineage commitments. Young Fronts reject human flight. Custodial Lineages reject conversion. Still Forecasts may accept bounded exchange.”

“Then the mature human path depends on cooperation you cannot promise.”

“Yes.”

Ceth's answer gave Taal no satisfaction. It strengthened the necessity case honestly.

The envoy addressed him in return. “If you fire a full burn, can you guarantee all humans survive landing?”

“No. Current models put transfer survival above every alternative, not at certainty.”

“Does your model include Manyweather resisting during the pulse?”

“Only bounded resistance inferred from the trial. We do not know your full capability.”

“Then your mature path depends on control you cannot promise.”

“Yes.”

The symmetry did not make the risks equal. It did prevent either side from describing uncertainty as a defect unique to the other.

Dima asked, “Do they all authorize you to refuse a burn?”

“They authorize Ceth to state that burn destroys their continuity. Young Fronts reject this assembly. Long Isobar rejects human authority but supports Article 9 evidence. No single Manyweather vote gives our body power to offer every district.”

A man near Sevi stood. “Then you cannot make peace.”

“Not for everyone. Neither can this room bind your sleeping people.”

The answer stirred anger because it struck a weakness the assembly had named

itself.

Sevi rose. "The sleepers have a mission contract."

Ceth turned toward her. "Did the contract include our deaths?"

"It included ground prepared for human survival. Your lineages arose inside the preparation system sent to make that ground."

"Does origin determine continued ownership?"

"It determines obligation. Patient Sower did not reach Ovid for its own future. People died building and launching it. Families died in the selection that followed. We were promised first ground after a voyage none of us could reverse."

Taal heard his own history inside her argument. Sevi knew about his family from public record. She did not use their names.

Iona said, "A promise based on hidden dispossession cannot complete itself unchanged."

Sevi faced the chamber rather than Iona. "Then change the plan without abolishing its purpose. We keep hearing what cannot be done to weather. Every day another sleeper moves into risk while the people awake are told restraint proves we deserve a place. I watched that weather take our craft. It knew the limit of our hull. It chose our route. Now its envoy stands in our assembly while forty thousand humans have no voice except a contract command appears ready to revise."

Someone called, "First ground."

The phrase repeated from three sections. Not a chant yet. A proposition seeking a body.

Sevi lifted the tablet with the pod image. "I want the burn avoided if another path lands everyone. I will not accept a path that saves our ethics by spending the sleepers. First ground means the mission ends with a human place to live, not permanent review aboard a failing ship."

Dima asked, "Are you organizing a motion?"

"Yes. Immediate deadline for alternatives. Burn remains lawful under necessity if none carries the full manifest."

Passengers around Sevi shared contact keys. A new public group appeared on the assembly board: FIRST GROUND, purpose listed as ENFORCE WHOLE-MANIFEST HABITATION WITHIN CRYOGENIC DEADLINE.

Taal could have ordered security officers not to lead political groups while in active service. Sevi had spoken as an injured participant and had not invoked rank. Suppressing her would turn a hard argument into evidence that review feared colonists.

"Lieutenant Rann," he said, "your security authority may not support First Ground organization or access control systems."

"Understood. I participate off duty and without command resources."

"Record that boundary."

She did.

Dima called for alternatives. Iona presented cloud habitat components: rillglass heat exchange, Sower aerostats, atmospheric spindles, drive-petal structural mass. The concept could avoid surface conversion but lacked a closed design. Niko appeared from Cryo with grease along one sleeve.

"Every percentage of radiator mass rillglass saves can become pressure shell," he said. "Every spindle assigned to weather control can hold lift. All six drive petals eventually detach and have independent power and structure. None of that currently forms a habitat. It forms parts."

A propulsion worker asked, "Could one petal hold a trial population?"

"After field collapse and spin transfer. Detaching one early risks the ark. Reusing all six ends any future interstellar capability and consumes our primary construction reserve."

"Survival generally consumes reserves."

"Permanent stranding consumes a future. We should name that while choosing it."

Dima moved to Pale. Sower archives showed excavated reserve tanks and industrial regolith works on Ovid's moon. Published estimates remained old and incomplete.

"Could Manyweather control Pale?" she asked.

Ceth answered, "Our embodied continuity occupies Ovid's weather and rillglass. We exchange Sower telemetry from Pale but claim no district there."

A First Ground member said, "Then survey it without them."

Iona replied, "Ceth could provide Sower archive context."

"We need a fallback whose evidence does not depend on the party refusing ground."

Ceth's body produced a soft pressure hiss. "Independent verification can reduce your uncertainty. Exclusion also communicates that our data counts only against burning, not toward your survival."

The First Ground member met that objection. "Human-only does not mean secret. Publish raw results to Manyweather. Let them challenge after collection. But send a crew whose route cannot be moved by the claimant we are negotiating with."

Taal recognized the proposal's strength. Pale lay outside Manyweather's claimed embodiment. A human-only survey could test whether lunar refuge offered independent capacity and reduce accusations that command had accepted Ceth's framing. If Pale failed, the failure would close a false hope before necessity review.

If it worked, it changed everything.

Niko said, "I can lead. We need structural, environmental, medical, and power inspection. Forty-eight hours from authorization to capacity report if transport receives priority."

"Mara?" Taal asked before remembering she had not yet revived.

Niko's face closed. "Scientific allocation may ask after she wakes. She does not join this survey by my decision."

Dima formulated the resolution:

NO IMMEDIATE BURN AUTHORIZATION.

CONTINUE ARTICLE 9 REVIEW.

DISPATCH HUMAN-ONLY SURVEY TO PALE WITH RAW RESULTS PUBLIC TO BOTH POLITIES.

REQUIRE VERIFIED WHOLE-MANIFEST CAPACITY OR EXPLICIT PARTIAL-CAPACITY LIMIT.

First Ground requested an amendment: retain burn readiness at current diagnostic state. Iona requested another: no spindle alignment through newly mapped inhabited lanes. Both entered the resolution.

The vote included awake civilian participants, with separate tallies for crew, revived passengers, and appointed sleeper-interest advocates. No tally pretended to represent the sleepers' personal consent. Across all three groups, immediate burn failed. The Pale survey passed by a wide margin.

Under the transit charter, the refusal placed a procedural lock on burn authorization until new evidence entered necessity review. Taal could break that lock under emergency command, but doing so would require a sealed casualty finding and public identification of the rejected alternative. The assembly had not disarmed him. It had raised the cost of acting without another record.

Taal still possessed emergency authority. Everyone waited to learn whether he would use it against the assembly.

"I accept the resolution," he said. "Burn systems remain at eighteen percent diagnostic, no higher. Mapped inhabited lanes remain excluded. Chief Saye receives transport priority for Pale. Human crew only. All raw findings mirror to the public archive and Manyweather."

Sevi asked, "If Pale cannot hold us?"

"Then its actual limit enters necessity review. No one will sell eight thousand places as rescue for forty-two thousand."

The number came from the oldest estimate and made the chamber shift. A refuge for some could become a selection process more violent than a burn debate.

Ceth said, "If Pale fails, you will say ground remains the only whole path."

"I will say the cloud design must carry everyone or admit whom it leaves," Taal answered. "You asked which deaths belong to prediction. This review will not hide them inside capacity percentages."

The assembly ended without reconciliation. First Ground left with hundreds of registered supporters and Sevi as its visible organizer. Iona carried the rillglass membrane back to controlled cold. Ceth's body paused at the chamber door until the system recognized their exception without another alarm.

On the command board, Pale changed from contingency to active mission. Niko's survey launch received a forty-eight-hour report clock. Burn readiness held. The public review retained power to refuse immediate fire, while Taal retained emergency authority if the ship crossed necessity.

A moon that could not move a corridor now had to answer how many bodies it could hold.

Chapter 11 — Eight Thousand on Pale

The descent engine coughed at eleven kilometers and shoved Niko hard against his restraints.

He watched the thrust trace drop through amber, touch red, and recover before the pilot could reach the manual split. Pale filled the forward ports, a gray curve scored by trenches and abandoned conveyor lines. Beyond it hung Ovid, too large and too blue for the cramped lander windows. A pale seam of cloud crossed the equator where Iona said a civilization lived.

“Feed valve stuck for point eight seconds,” pilot Sel Aven said. “It has reconsidered.”

“Machines do that when threatened with maintenance.” Niko kept one hand on the propulsion isolate. “Give it another chance to develop character and I shut it down.”

Behind him, reserve engineer Kavi Orrel laughed once, without much conviction. The fourth seat held Venn Hal, a medical systems officer who had brought six sensor cases and the expression of someone already measuring a room for beds.

They had left Meridian Promise with seventeen days remaining on the cryogenic transfer clock. Command called this a fallback survey. First Ground called Pale the obvious answer. Niko had heard both descriptions in the assembly and trusted neither. A fallback had to carry weight. An answer had to survive arithmetic.

The lander crossed the terminator into hard sunlight. Patient Sower’s old works appeared beneath them: three excavated vault mouths, a fan of regolith spoil, two pressure domes sunk to their shoulders, and a field of radiator spars aimed at black sky. Most machinery had not moved in sixty years. Sower’s orbital maps still marked the site RESERVE HABITABILITY WORKS P-4, as if a label could keep seals supple.

Sel set them down between painted hazard bars. Dust rose in a slow sheet and remained suspended long enough to turn the landing lights into white columns.

Niko waited through the pressure checks. His suit showed no external oxygen, no meaningful nitrogen, and a daytime surface temperature that could cook exposed cabling before a technician finished regretting it. Pale offered vacuum, radiation, and rock. Compared with a dying cryo lattice, those counted as stable conditions.

The outer hatch opened on a landscape without weather.

His boots struck the ladder, then gray powder. Gravity pulled at roughly one fifth of ship standard. Every tool wanted to become a projectile. He clipped the diagnostic case twice before trusting it. Kavi bounded toward the nearest service

mast while Sel secured the lander, and Venn stood still for five seconds, looking up.

Ovid occupied half the sky.

No display aboard the ark had prepared Niko for the planet's apparent weight. Cloud bands folded around one another in blue, white, and bruised silver. The atmosphere looked close enough to fall. Along the equator, the blue front held a color too deliberate for distance.

Venn lowered her visor shade. "Eight thousand?"

"That came from Sower's preliminary inventory," Niko said. "We are here to find out what the number costs."

They crossed to Vault One. The outer door accepted Sower credentials but stalled after twelve centimeters. Niko and Kavi fitted a hand jack into the gap. In weak gravity the jack's resistance traveled through his shoulders rather than into his boots. Metal scraped. A strip of seal tore loose and floated between them like black skin.

"Outer seal condemned," Kavi said.

"Record it as replaceable."

"It came off in my hand."

"So did half our cryo manifold, and command still calls that a ship."

The opening widened enough for them to pass. They entered a lock chamber built for construction machines, not people. Kavi patched the seal channel with expanding braid. Niko connected portable power to the inner controls and heard pumps wake under the floor, one after another, each note rough with disuse.

Pressure climbed to twelve kilopascals and stopped.

A warning populated his wrist display: RESERVE GAS BELOW COMMISSIONING FLOOR.

Venn looked through the inner hatch at darkness. "Can we proceed in suits?"

"We can proceed until the structure tells us not to."

They cycled through.

The vault descended in terraces around eight cylindrical tanks. Frost furred the lower pipework despite the dead air. Sower had mined oxygen from Ovid's upper atmosphere during early preparation, separated buffer gases, and stored the reserve here against a failed planetary conversion. The tanks looked enormous until Niko pulled their certified volumes onto his visor and divided by 42,318.

He did the calculation twice because the first answer felt insulting.

Kavi reached the manifold ahead of him. "Two tanks show zero."

"Isolation or loss?"

"Unknown."

Niko opened the service history. Forty-three years of maintenance entries ended

in 2329 with a note from Osric Pell's earlier instance: PRIORITY REALLOCATED TO EQUATORIAL CONTINUITY WORKS. The phrase held more politics now than it had when an expert system wrote it.

He touched the first tank housing. Vibration reached his glove from the portable pumps, nothing more. "Ultrasonic sweep. We prove inventory before anyone promises it."

They worked outward. Kavi tested welds. Sel deployed radiation counters and marked shielding thickness. Venn followed the air lines to the buried habitation galleries. Niko sampled each tank through valves that resisted, leaked, or produced gas contaminated with sulfur compounds and compressor oil. One empty tank had ruptured into the surrounding regolith. The other held frozen carbon dioxide beneath a failed sensor.

By the end of the first hour, six tanks carried recoverable inventory. Four required internal lining before anyone could trust them above half pressure. Every gasket had aged in vacuum. The central compressor needed bearings, control electronics, and a motor winding that Meridian Promise could provide only by stripping two cryo service units.

His suit clock showed sixteen days, twenty-one hours until the transfer limit. The number had stopped feeling like a deadline and started behaving like gravity.

Venn called from Gallery B. "I need you here."

Her beacon lay eighty meters below. Niko and Kavi took a freight incline whose rail car had frozen halfway down. They moved by handholds along the wall, boots finding occasional traction in the dust. The gallery opened behind an insulated bulkhead. Venn had forced its inspection shutter and aimed her lamp through.

Rows of folded bunks covered the chamber walls. Air ducts ran beneath a low ceiling. Emergency water bladders occupied a rear recess, flattened and brittle. It resembled a shelter designed by someone who believed bodies could be packed according to volume alone.

"How many?" Niko asked.

"Two thousand in this gallery at emergency density. Four galleries." Venn pointed toward the sanitation spine. "If the reclaimers perform at rating. If respiratory illness does not spread. If we accept hot-bunk rotation and no surgical isolation."

"Show me the medical load."

She sent him the model. Eight thousand residents consumed the certified reserve in one year once leakage, food production, water loss, and machinery heat entered the equation. At ten thousand, carbon dioxide removal failed within eleven weeks. At 42,318, the tanks did not matter. Even with impossible sealing and rationing, the pressure reserve fell below survivable limits in thirty-nine days. Food ended sooner.

Niko checked her assumptions against Sower's planning files. They matched within four percent.

"People will say we can expand," Kavi said.

"People are correct," Niko answered. "The question they leave out concerns time."

Beyond Gallery B, Pale held enough excavatable volume for a city. Rock did not equal habitat. Pressure skins had to be fabricated. Heat had to be rejected. Nitrogen had to be captured, transported, and stored. Food loops had to mature without fungal collapse. Radiation shielding needed meters of regolith over every occupied space. Meridian Promise carried equipment for surface construction under Ovid's atmosphere, where machines could dump heat and draw working gases. Here every system had to bring its own environment.

Niko built a conversion schedule on his wrist. He assigned all six drive petals as power and field support, every available fabrication line, and half the awake workforce. The model reached 42,000 beds in fourteen months. Cryo gave them sixteen days and change.

He changed the staffing assumptions until they became cruel. Nine months.

He allowed catastrophic equipment attrition and stripped the ark's habitats for pressure skins. Seven months, followed by no viable ship.

Nothing reached three weeks.

Venn watched the figures revise. "Eight thousand for one year."

"With radical expansion starting now, maybe twelve thousand by the end of that year."

"And everyone else?"

He closed the projection. "Still needs somewhere to breathe."

A sharp impact traveled through the gallery floor.

Kavi's lamp swung toward the incline. Fine dust sifted from an overhead seam. Sel's voice burst over comms, clipped by static. "Solar warning. Particle front arrived early. Surface dose climbing. Lander has lost one feed from the reserve mast."

Niko brought up the site schematic. Old radiation shutters should have sealed the galleries. Three reported open, including the freight access above them.

"Time to unsafe dose?"

"Twenty-six minutes outside. Perhaps forty in that gallery if the roof matches the plan."

The roof did not match any inspection less than sixty years old.

Niko sent Kavi to the shutter motor and followed Venn toward the gallery's dosimeter rack. Its passive tiles showed a darker history near the western wall. Shielding had shifted or never met specification. They could retreat to the lander,

but the surface crossing would consume twelve minutes and place them in the rising front. The lander carried shielding for four, not a sustained storm. Vault Two, thirty meters deeper, offered certified refuge if they could open the connecting tunnel.

"Sel, abandon surface work and bring the portable core," he said. "Use the north trench. Less exposure."

"Already moving."

Kavi opened the shutter control cabinet. "Motor drive is dead."

"Mechanical release?"

"Behind the shutter."

"Elegant."

Niko examined the freight system. The frozen rail car stood on the incline above them, loaded with modular pressure panels. Its brake remained engaged. The shutter hung at the upper mouth, a slab of composite and regolith shielding intended to descend on side tracks. If they released the rail car and controlled its fall, its mass could pull the shutter down through the old counterweight linkage. If they lost control, forty tonnes of panels would reach the gallery and convert their refuge into debris.

Kavi traced the linkage. "Sower used the car drive as an emergency lowering assist."

"Can we power it?"

"Not before the particles arrive."

"Can we brake it?"

"With the lander's descent controller."

Sel came through the inner lock carrying the portable power core against her chest. Pale's gravity made the unit manageable, not light. "You are not taking apart my lander."

"Only a controller."

"The one attached to the engine that coughed."

"It has already demonstrated unreliable character."

Her visor hid her face, but he heard the breath that might have been a laugh. "Nine minutes to red surface dose."

They moved.

Sel returned to pull the controller. Kavi climbed the incline to rig the brake leads. Niko and Venn dragged pressure panels away from the rail's end and opened the path to Vault Two. The connecting door had power but no atmosphere on its far side. That did not matter while they wore suits. What mattered lay beneath its threshold: the cable trench for the reserve distribution spine.

Niko removed the floor plate. Three thick superconducting trunks ran toward Vault Two and on to the surface mass drivers. Pale could not shelter the colony, but its buried grid remained mostly intact. The reserve tanks, fabrication vaults, shielding galleries, and launch rails formed a working industrial yard waiting for parts and labor.

Not refuge. Capacity.

He tagged each trunk for full diagnostic mapping.

The dose alarm shifted from yellow to orange. Static scratched every channel.

Kavi called, "Brake leads connected. Car release has no remote."

Niko saw the implication at once. Someone had to stand beside the rail car and pull the manual dog, then clear the incline before forty tonnes began to move.

"I am closer," Kavi said.

"No. Give me your suit dose."

"Still green."

"Mine too. Give me the number."

A pause. "Sixteen millisieverts."

Niko had nine. Kavi had spent longer near the thin roof. "Come down. I take release."

"You are mission chief."

"Which means I know the brake model."

"You read the manual six minutes ago."

"An excellent manual."

Niko climbed before Kavi could turn hierarchy into an argument. Each pull along the handrail lifted him a meter. Radiation warnings crawled higher on his visor. At the rail car, he found the manual dog under a housing fused by dust. He struck it with a wrench. Nothing moved.

Below, Sel wired the descent controller to the old brake. "I can hold a maximum of twelve kilonewtons before this improvisation becomes plasma."

"The car needs nine."

"According to a plate printed before my grandmother's grandmother learned to swear."

"Your confidence sustains me."

He struck the housing again. A corner broke free. The release lever appeared beneath it, corroded but whole.

Venn's voice came softly. "Surface is red."

Niko wrapped a tether around the incline handrail. "Ready brake."

"Brake ready."

He pulled.

The lever moved halfway and stuck. He put both hands on it and braced one boot against the rail. His shoulders protested. The lever came free with no warning.

The car dropped six centimeters and slammed against its brake.

Sel swore. Kavi shouted a load reading. Niko pushed himself off the rail car as it began to creep. The tether snapped taut, swinging him toward the wall. He caught a handhold and flattened himself while the car passed close enough for one pressure panel to strike his equipment pack.

Below, the controller whined. The rail car accelerated, slowed, then accelerated again. Its movement hauled the shutter counterweight. From overhead came a grinding roar as the shielding slab entered its tracks.

"Brake temperature critical," Sel said.

"Let it run to eleven."

"It is at eleven."

"Then let it run to the number after eleven."

The controller casing flashed blue. Sel cut power. Mechanical shoes seized against the rail. The car stopped three meters above the gallery floor, swinging on compressed suspension. At the upper mouth, the shutter settled into its seal with a final impact.

Radiation readings began to fall.

For several seconds nobody spoke. Niko descended past the rail car and found Sel sitting against the wall with the ruined controller between her boots.

"My lander," she said.

"We have a second controller."

"On the other descent engine."

"The reliable one."

"That engine has now developed anxiety."

They crossed into Vault Two while the particle storm struck Pale. Charged grit hissed through their comms. Beneath twelve meters of regolith, dose rates settled into tolerable amber. The vault held dormant fabricators, ore separators, and modular launch cradles. Most units needed overhaul. None depended on an atmosphere.

Niko worked for four more hours.

He mapped power trunks and pressure volumes. Kavi sampled the fabricator feedstock. Venn marked two galleries suitable for surgical wards once sealed. Sel inspected the mass drivers and found one rail aligned with Ovid transfer trajectories. A module launched from Pale could reach the upper cloud works using a fraction of the ark's maneuvering fuel. Supplies too dangerous to lower through Ovid's weather could be assembled under vacuum and sent down in hardened

shells.

The reserve site had failed as an answer and become useful as a tool.

Venn made him walk through Gallery C before they left. Its roof held the deepest shielding, and old wall mounts could take isolation tents without drilling fresh anchors. She placed imaginary patients in rows: radiation injuries nearest the lock, unstable sleepers beside the power spine, surgical beds behind two pressure doors. Niko followed her gestures until the empty chamber held a hospital in his mind. Eight thousand did not have to mean eight thousand people abandoned on a moon. It could mean room borrowed for the sick while the healthy built pressure volume elsewhere.

"Can you make the transfer gentle enough?" she asked.

"Not yet."

"That is not what I asked."

He studied the freight dimensions and the launch acceleration from Sel's rail survey. A medical module could ride within limits if its cradle spread load through six points and if someone rebuilt the rail controller they had just burned.

"Yes," he said. "With work."

Venn tagged the gallery MEDICAL PRIORITY rather than HABITATION. One word changed the allocation before any patient arrived.

When the storm passed, they returned to the lander under a sky black enough to show Serein beside Ovid's bright limb. Sel launched on one engine, keeping the damaged feed isolated. Pale fell away beneath them.

Niko opened a channel to Meridian Promise. Taal, Iona, and the assembly recorders waited on the other end. He sent the tank survey, the habitat model, the radiation incident, and the construction inventory before speaking.

"Pale supports eight thousand people for one year," he said. "That assumes immediate seal replacement, strict rationing, and transfer of two ark fabrication lines. It cannot accept the full population before cryogenic failure. Not under any credible labor, power, or pressure budget."

A burst of voices rose from the assembly feed. Taal cut them down. "Can expansion make it a settlement?"

"In seven to fourteen months, with losses we cannot price yet. We have sixteen days. Pale does not remove the need for Ovid."

Iona asked, "What does it give us?"

Niko looked at the moon through the aft port. The old trenches made dark strokes across its surface.

"A shielded hospital for eight thousand. Vacuum fabrication. Reserve gas. A launch yard with one usable Ovid rail. Enough industrial capacity to stage construction somewhere else."

“Somewhere else,” Taal repeated.

Niko placed Ovid and Meridian Promise on the same systems diagram. Between them he drew a blank work zone in the temperate clouds. He did not name the structure that might fill it. No design yet carried the loads.

“Pale can help us build,” he said. “It cannot become the place where we hide from choosing.”

The assembly record changed classification while he watched. FALLBACK REFUGE became STAGING ASSET P-4. Command released the two fabrication lines for survey preparation, not evacuation. Across the ark, eight thousand imaginary beds disappeared from the survival plan.

No one could promise Pale to the other 34,318 people now.

Chapter 12 — The Sister Who Woke

Mara woke with her hands closed around a tube in her throat.

Niko caught her wrists before she tore it free. Her eyes opened without recognition, pupils wide under the revival lights, and her whole body bucked against the suspension web. The ventilator alarm climbed. Frost melt shone on her cheeks.

“Mara. Do not pull. Breathe with it.”

She struck his forearm with surprising force. A nurse reached for sedation, but Niko shook his head. Mara had spent 143 years inside a pod whose lattice now leaked timing errors into every thermal cycle. More drugs would make the confusion easier for the room and harder for her lungs.

He leaned close enough that she could see one face. “Three breaths. Then they remove it. One.”

Her chest fought the machine.

“Two.”

Recognition arrived as anger. It had always moved quickly in her.

“Three.”

The respiratory nurse released the cuff and drew out the tube. Mara gagged, coughed fluid into a suction mask, and dragged air as though she disapproved of its quality. The monitors settled by degrees. Niko let go of her wrists.

Her first word came scraped thin. “Late?”

“We arrived.”

“How late?”

“One hundred forty-three years in transit. Four days ahead of the nominal arrival window.”

She shut her eyes. “Not what I asked.”

He should have expected that. “Your scheduled revival moved forward by eleven days.”

“Why?”

The nurse touched his shoulder. Questions could wait through the neurological screen, the marrow infusion, and the warm electrolyte cycle. Mara watched the contact. Her gaze traveled from the nurse’s hand to Niko’s face and stayed there.

“Why?” she repeated.

Niko gave her the shortest truthful answer. “The cryogenic lattice is failing. Your

pod entered the high-risk queue. Your structural-biology work may also help us.”

A weak laugh hurt her into coughing. “You made it sound almost fair.”

They moved her from the revival cradle to a pressure bed. Around them, Medical Bay Four ran at triple occupancy. Curtains divided six fresh wakes from two unsuccessful ones. One body remained under a thermal sheet while orderlies prepared the transfer capsule. Thirty-seven people had died across the transit before arrival accounting closed. Since then, every bad revival threatened to change the count again.

Mara saw the covered body. “Who?”

“I don’t know yet.”

“You usually know numbers.”

“I know too many.”

Her eyes opened again. “Did you choose me?”

The question reached past every explanation he had prepared.

“Your pod had eleven-point-two percent phase drift,” he said. “Structural biology placed you in the fourth critical-skills cohort. Medical ranked the wake as necessary within eighteen hours.”

“Did you choose me?”

“I signed the schedule.”

She turned her face away.

Niko spent the next three hours where the medical staff allowed him: beside the bed during cortical checks, outside the screen during invasive work, at the bay terminal when his engineering queue became too loud to ignore. He approved replacement coolant runs, rejected a proposal to reduce revival warming time by six minutes, and routed one of Pale’s future galleries for isolation use. Every task had a person attached to it. Every person became a reason someone else waited.

Mara failed the first standing test. Her knees folded before she cleared the bed. Niko caught her under the arms, and she swore into his shoulder.

“Useful gravity,” she said.

“Point seven ship standard.”

“Still showing off.”

The nurse lowered her into a chair. “Five minutes upright.”

Mara’s hands trembled against the blanket. Her face had lost the roundness Niko remembered from launch preparation. Cryostasis did not age a body much, but it took payment in small deficits: brittle capillaries, muscle stripping, errors in memory retrieval. She looked thirty-four and newly unfinished.

On the wall display, Ovid rotated beneath Patient Sower’s orbit. The blue front crossed the image in false-color overlays. Mara watched it between tests.

"What happened to the landing plan?" she asked.

"We found inhabitants."

"Human?"

"No."

"Native?"

"That question starts arguments."

"It usually means the categories are poor." She studied his expression. "You need my work because of them."

"We need your work because Ovid's native cloud organisms exchange heat through salt-silicate lattices. The inhabitants coupled their computation to those organisms."

"Computation?"

"Embodied forecast lineages. Persistent people, according to the evidence."

"According to you?"

"According to Iona Vale. According to Stewardship Article Nine. According to one of them, who built a body in Sower's service bay and asked us not to erase everyone."

Mara absorbed that without wonder. She had always distrusted wonder when a mechanism remained available. "Show me the samples."

"You are four hours awake."

"And already disappointed by management."

"Medical has not cleared you to cross the bay."

"Then bring the work here."

He had anticipated the request. That irritated her too.

A sealed sample stage arrived twenty minutes later under Iona's authorization. Three rillglass fragments rested in separate microclimate cells: translucent fans no larger than a thumbnail, each branching around a core of trapped blue dust. The material had come from Iona's descent beneath the front. One fragment remained metabolically active. Its edges brightened whenever the cell's sulfur concentration rose.

Mara forgot to be weak for nearly a minute.

She asked for thermal imaging, spectral absorption, gas-exchange logs, and the pressure history from collection. Niko arranged the displays around her chair. Her trembling fingers missed the first control twice. On the third attempt she expanded a heat map and began to read.

"Your instruments average across the colony," she said.

"They are survey instruments."

"They are hiding pulses. Give me raw frames."

He retrieved them from Iona's expedition packet. The image resolved into brief thermal contractions moving from the rillglass edge toward its dust-bearing core. Each pulse released heat into the surrounding gas, followed by sulfur uptake and a slower radiative cooling phase.

Mara counted intervals under her breath. "This is not passive regulation."

"Ceth says rillglass reproduction stabilizes Manyweather continuity."

"Ceth?"

"The envoy."

"You gave an atmospheric federation one short name?"

"They selected it for human use."

"That is marginally less embarrassing." She enlarged the cell telemetry. "Raise external temperature by two degrees."

"The collection protocol limits change to point five."

"Then point five."

Niko altered the stage. The rillglass fan contracted. Its central dust brightened, and heat traveled along the salt-silicate ribs into a thin boundary layer. Instead of accumulating, the added energy drove a faster sulfur exchange.

Mara requested another half degree. The response repeated with a shorter interval.

"It metabolizes a gradient," she said. "Not heat alone. Difference."

"Useful for what?"

Her look informed him that chief systems engineers should occasionally think. "A structure suspended in atmosphere has cold exterior flow and warm occupied volume. We spend power moving heat from one to the other. This organism already uses that exchange to maintain chemistry."

"Organism and forecast dust together."

"Yes. Separate them and what happens?"

"The burn pulse detaches the dust. Likely collapse of both."

"Then stop calling the dust payload."

"I do not."

"You did six minutes ago."

He replayed his wording and found she had him. "Habit."

"Habits built the mission."

She asked for the collection temperatures beneath the blue front. Niko sent the expedition profile, but he removed Iona's injury telemetry and the sections marked by contact security. Mara scrolled until a gap in the timestamps exposed him.

"What did you cut?"

"Crew medical data."

"Who authorized you to filter the environmental record?"

"Iona's blood oxygen does not affect your model."

"Her suit heat might. Her body entered the same exchange volume as the sample. Give me the uncut thermal channels or explain the omission in a methods note."

The demand sounded like their mother at a laboratory review, though neither of them had heard that voice for 143 years. Niko restored the thermal channels and masked only Iona's identity. A brief surge appeared at the moment a storm breach forced Iona against the rillglass mat. The active colony had drawn heat away from her suit, moved it laterally across nearly two meters, then released it into a colder downdraft.

Mara sat straighter. "There. It responds beyond its own body."

"Ceth said the district repaired the breach with her."

"You omitted that too."

"I gave you measurements."

"You gave me measurements selected to keep me inside your preferred question."

"The question concerns a thermal interface."

"No. Your question concerns whether I can supply a component. Mine concerns what kind of relationship produces the component."

She requested pressure data from both sides of the breach. Niko layered it over the heat trace. The rillglass did not merely conduct energy. Forecast dust had shifted local flow, creating a cold sink exactly where the colony could use it. Biology, computation, and weather control had cooperated across scales.

Mara drew three linked loops on her tablet. Human habitat heat fed rillglass exchange. Rillglass sulfur metabolism fed the blue-front chemistry. Forecast control maintained the gradient and received waste heat it could route into atmospheric work.

"Aerostats usually dump heat as a burden," she said. "Here occupied volume could supply a regulated input. The inhabitants might value part of what keeps us alive."

"Might."

"Yes, might. Do not sound wounded by accurate uncertainty."

Niko ran a preliminary radiator comparison. If the observed transfer rate scaled without damaging the colonies, rillglass exchange could remove nearly sixty percent of the habitat radiator mass assumed by surface-derived designs. Less radiator mass meant more shielding, water, and pressure structure. It also meant

no human habitat could operate independently of the living cloud ecology.

He showed her the result.

Mara did not smile. "Do not publish sixty percent. One fragment under a controlled gradient does not scale to a city."

"You found the mechanism."

"I found a question worth risking sleep over."

Her pulse monitor rose. The nurse told her to rest. Mara refused until the active fragment completed three more cycles. Niko watched the numbers and recognized the same bargain he made with failing machinery: let it run slightly beyond limits because stopping lost information. Applying that bargain to his sister felt obscene.

He shut down the displays.

Mara stared at him. "Turn them back on."

"No."

"My work just produced a viable thermal interface."

"Your heart rate is one-forty."

"My heart has complained about your decisions since childhood."

"Medical limit is one-twenty-five."

"Whose limit?"

"The physician responsible for keeping you alive."

"And you enjoy having a professional accomplice."

The nurse stepped between them with practiced neutrality. "Bed. Now."

Mara let them move her, but she did not release the point. As the pressure bed adjusted around her, she said, "You woke me because my pod was failing and because I might be useful. Both can be true. What you do not get to decide is which truth I am allowed to work with."

Niko checked the blanket seal because it gave his hands a task. "You were hypoxic during revival."

"For ninety seconds."

"One hundred seventeen."

"Thank you for proving my complaint."

He left before the argument became a medical event.

Outside Bay Four, the cryogenic queue covered an entire wall. Amber units had doubled since his Pale departure. Thirty-one pods now required waking inside forty-eight hours, while the medical bays could safely process twenty-two. Niko moved technicians, delayed low-risk revival cycles, and sent a request for temporary beds in an unfinished habitation drum. No rearrangement created nine missing places.

Sevi Rann stood at the far end of the corridor beside a family viewing panel. Security officers did not belong in medical unless a wake became violent or grief turned public. She had removed her helmet and held it under one arm. Through the panel, a sleeper's revival team worked behind opaque screens.

"Problem?" Niko asked.

"Her name is Dera Voss," Sevi said. "Power technician. She trained half my section before launch."

The monitor above the panel showed severe lattice injury.

"Family?"

"None awake."

Niko read the prognosis. "They are doing everything available."

"That phrase should cost more to say."

"I know."

Sevi looked toward Mara's bay. "Your sister made it."

"She is awake."

"That is not what I said."

Before he could answer, the viewing panel cleared. A physician stepped out and gave Sevi the kind of silence that preceded a count. Sevi went inside. Niko returned to his queue because staying would intrude and leaving felt like cowardice.

Dera Voss died eighteen minutes later.

Sevi emerged carrying Dera's identification strip in a sealed evidence sleeve. Regulations assigned personal effects to Family Continuity, but no relative had entered the waking queue. She held the strip as if procedure had forgotten its weight.

"She repaired my first field compressor," Sevi said. "Made me dismantle it again because I had tightened the couplings in the wrong order."

Niko had no reply that did not reduce Dera to instruction or loss. He opened the skills register and found six technicians who carried her qualification, four still asleep in unstable pods.

"Will her place move someone else forward?" Sevi asked.

"Medical capacity, yes. Her death does not create a safe pod."

"So one bed opens while the queue stays broken."

"Yes."

Sevi looked through the panel at the emptying room. "People hear review and think someone has decided time belongs to arguments."

"Time belongs to the failing equipment."

“Then make command speak that plainly.”

She walked away before he could ask what plain speech would make her do.

The ark’s living count changed from 42,318 to 42,317 pending formal classification. The thirty-seven transit deaths already included bodies whose final failure had only now been confirmed by revival; Dera’s status required audit before anyone altered the canonical manifest. Niko ordered that distinction preserved. Numbers could not be allowed to blur merely because command disliked what they did to morale.

When he returned to Mara, she had obtained a tablet from someone less resistant. A structural sketch covered the display. It showed a double membrane around an air volume, rillglass colonies seeded through the outer layer, and channels for forecast dust to regulate sulfur and heat exchange.

“You should be asleep,” he said.

“You should be less predictable.”

He examined the sketch despite himself. “No primary support.”

“This solves metabolism, not load.”

“No radiation layer.”

“Add one.”

“No way to keep the colony attached during pressure shear.”

“Your profession may contribute something eventually.”

He sat beside the bed. “Mara, the structure you are drawing would hang in Ovid’s upper atmosphere.”

“Yes.”

“Manyweather controls those bands.”

“Then we ask.”

“They may refuse.”

“Then the design fails for a legitimate reason rather than because we never drew it.”

He zoomed into her membrane channels. The thermal interface could reduce radiator mass dramatically. Meridian Promise carried enough pressure fabric for surface habitats, but surface units assumed foundations and external atmosphere. Suspended cells needed frames, lift, active balance, and weather cooperation. Pale’s fabricators could form components under vacuum. Patient Sower’s spindles could shape local pressure if Manyweather consented. The ark held six drive petals built to distribute loads around an interstellar field.

The pieces did not form a structure yet. They had begun occupying the same diagram.

Mara watched him see it. “How many people fit on Pale?”

"Eight thousand for one year."

"Not enough."

"No."

"How long until the pods fail?"

"Sixteen days, nine hours to the transfer limit. Some will fail earlier."

"And command's other option?"

"A burn pulse. It creates a surface corridor and kills Manyweather. It probably kills most rillglass continuity as well."

She touched the active sample cell through its sealed cover. The fragment responded to heat from her fingers by brightening along one edge.

"So this is not a material problem," she said.

"It includes material."

"It includes a negotiation you keep trying to phrase as engineering."

"Engineering decides whether a negotiated promise can hold air."

"Good. Then do that part and let people decide whether to enter it."

He heard the accusation beneath the plural.

"You think I should not have signed your wake order."

"I think you should stop pretending the signature happened to you."

"Your pod carried a lethal drift."

"Then say you chose to wake me because you wanted me alive."

"Medical ranked you for immediate revival."

"Niko."

The room's machines made avoidance impossible. Every breath appeared as a trace. Every heartbeat registered between them.

He said, "I wanted you alive."

"Of course you did." Her voice softened, which hurt worse. "I wanted that too. But you also moved me ahead of somebody."

"Your expertise may save them."

"May. That word belongs in the sentence."

He looked through the glass toward the corridor where Sevi had waited. Dera Voss's classification still sat unresolved in the manifest. Niko had not awakened Mara from sentiment alone. He had not excluded sentiment either. A clean motive existed only in reports written after decisions.

"What do you need from me?" he asked.

"Access to the complete rillglass data. A workstation Medical will tolerate. No use of my name in assembly arguments without my approval."

"That last condition may be hard to enforce."

"Then enforce it loudly."

"And?"

Mara looked at the fragment. Its thermal pulse traveled through blue dust and translucent ribs, a living exchange neither component could perform alone.

"I want to meet Ceth."

"When you can stand."

"No." She raised a hand before he could convert concern into command. "When Medical clears me for contact, I meet them as a structural biologist. Not as your sister. Not as a high-risk sleeper displayed to make a point. Not as proof that humans deserve anything."

Niko opened the scheduling system. Ceth's embodied visits remained suspended pending atmospheric conditions and Manyweather's internal review. He sent a formal request under SCIENTIFIC EXCHANGE, with Mara Saye listed as principal investigator and himself nowhere in the purpose field.

"Requested," he said.

"Show me."

He handed her the tablet.

Mara read every line before authorizing it with a shaking thumb. The request passed from Medical Bay Four to Iona Vale, then into Patient Sower's bounded contact channel.

For the first time since revival, no one else had signed for her.

Chapter 13 — First Ground

The sleeper behind the glass opened her eyes and did not wake.

Sevi Rann stood beside the revival console while the medical team warmed Tessa Om through the last four degrees. Tessa's pupils responded. Her fingers curled around nothing. Neural traces climbed, broke into separate rhythms, and failed to join. The physician called her name twice, then ordered a slower perfusion.

On the public side of the glass, twelve people watched without speaking. Most wore work clothes over partial pressure liners. One held a First Ground strip, green cloth printed with a black horizon, folded inside his fist rather than raised.

Sevi had been assigned to keep the corridor clear.

Security's written concern involved crowd obstruction and interference with medical work. The actual concern stood in every witness's face. They had been told that review required seven days, that Patient Sower's inhabitants might possess rights, that Pale could hold eight thousand for a year, and that the ark still carried 42,318 living people. Each fact arrived through a different official voice. None explained what a family should do while a sleeper's mind failed to assemble.

The physician adjusted the cortical field. Tessa's left hand began to shake.

A woman near Sevi whispered, "She taught pressure farming."

Sevi knew. Tessa had trained the security intake cohort in emergency algae cultivation. She had described food systems as disciplined appetites: nitrogen wanted a cycle, light wanted a surface, people wanted more certainty than plants could offer. During launch preparation, she made every officer culture a tray of greens and eat the failures.

The neural rhythms diverged again.

Sevi watched the physician's shoulders change. No alarm sounded. Medical had learned to keep bad news quiet until it could be assigned a form.

"Tessa Om remains physiologically stable," the physician said over the viewing channel. "Cortical integration has not reached conscious threshold. We will continue assisted emergence."

"How long?" someone asked.

"Unknown."

The man with the folded strip opened his hand. FIRST GROUND faced the glass.

Sevi should have ordered him to put it away. She did not.

Her shift ended forty minutes later. Tessa still breathed under machine control.

The count had not changed, which allowed command to say no one had died. Sevi returned her helmet to the security locker and found three messages from Lieutenant Commander Edris, all requesting presence reports on First Ground gatherings. A fourth message ordered continuous monitoring of control-seed staging while burn preparation remained authorized.

She read that one twice.

Control seeds served as hardware authorization kernels. Patient Sower accepted terraforming commands only when a seed authenticated the command path at a spindle or dust-injection node. Burn preparation had moved twelve seeds from deep stores to Staging Vault Six so technicians could inspect them. Commodore Taal had not ordered a pulse. He had ordered readiness.

Readiness meant a possible act had acquired clean connectors, charged cells, and a labeled shelf.

Sevi walked to the mess without answering Edris. First Ground occupied two tables near the aft wall. The movement had no elected head, despite the assembly feeds naming spokespeople as if fear required an office. People came wearing the green strips when a pod failed, when a landing vote stalled, or when a child asked why the blue planet remained forbidden.

Ossin Ter waved her over. He supervised cryo power distribution in Bays Six through Nine. Since Dera Voss's death, his uniform had remained wrinkled at one shoulder where she had once torn off an obsolete qualification patch.

"You are on duty?" he asked.

"Not now."

"That answer sounds rehearsed."

"It is a regulation."

At the table sat Lale Pryn from Sower staging, agricultural planner Hec Varo, and two people Sevi knew only from corridor reports. No one spoke until she sat.

Ossin pushed a tablet toward her. It showed Tessa Om's wake trace without a name. "How many of these until review ends?"

"Cortical integration can recover over hours."

"How many?"

"The cryo deadline remains fifteen days."

"That is not what I asked."

Sevi had heard the sentence twice in two days, first from Niko, then from grief. "No one has a reliable count by day."

Lale tapped a schematic onto the table. It depicted an atmospheric spindle and a narrow column beneath it, marked for human descent. "Sower's original corridor sequence uses distributed burn across twelve nodes. Full conversion needs all twelve. A local opening can run on two."

Sevi did not touch the tablet. "Where did you get this?"

"I stage the hardware."

"You stage components. You do not hold command models."

"They came with the seed test package."

"Then reading beyond your task violates access."

"So does letting people die while a forecast asks for more time."

Hec Varo leaned forward. "A narrow corridor does not require a planetary burn. Two nodes, low duration, landing area under fifty kilometers. We establish ground, transfer the most fragile sleepers, and continue review from safety."

"Whose ground?" Sevi asked.

"Uninhabited surface."

"The atmosphere above it may not be uninhabited."

Ossin's mouth tightened. "You heard Ceth. Their lineages occupy the equatorial front. This site lies twenty-one degrees north."

"Manyweather's weather control crosses districts."

"Then they can move it."

Sevi looked around the table. Nobody here spoke like a killer. That made the proposal harder to dismiss. Hec had three children asleep in Bay Two. Lale had spent six years awake maintaining a ship meant to deliver strangers. Ossin had just watched his mentor leave medical under a sheet. They had reduced the pulse because reduction felt like mercy.

"What happens to forecast dust inside the corridor?" she asked.

Lale answered too quickly. "Factory reset within the active column."

"Minds?"

"No named lineage appears on the site map."

"That did not answer me."

"We do not know."

There it stood: not innocence, but the gap they intended to use.

Sevi rose. "Do nothing with this. Send me the complete package."

Ossin caught her sleeve. "So you can report us?"

"If I meant to report you, security would already be here."

He let go.

Hec followed her out of the mess. He carried no green strip, only an agricultural service badge worn smooth at one corner. At the next junction he stepped in front of her.

"You think we are looking for permission to kill them," he said.

"I think you built a plan around information the plan does not measure."

"My youngest daughter's pod has a coolant lesion. Bay Two keeps moving her wake forward and back because every earlier emergency takes the bed."

"What is her name?"

"Rin Varo. Seven at launch."

Sevi opened the queue on her wrist. Rin's unit sat in amber, scheduled thirty hours out, with a twelve-percent probability of phase loss before revival. Hec watched her read.

"You know what that number does to a parent?" he asked.

"It gives Medical a risk order."

"It gives me a chance of rehearsing her death every time the schedule changes."

The corridor carried off-shift workers around them. Two recognized Sevi and slowed. Hec lowered his voice.

"First Ground did not start because we hate something in the clouds. It started because every plan on this ship ends with ground. Farms need pressure. Children need radiation mass. We crossed 143 years for a place where survival does not depend on one hull."

"Ovid already has survival systems."

"Then make room among them."

"That sounds different from taking room only until you stand inside it."

His face changed. "You had a family in the selection?"

"No."

"Then you do not know what people surrendered."

Sevi's mother had died in the Recife ration violence four months before selection closed. Her father refused a berth after Sevi received one, saying the ark should not carry old grief as ballast. She had learned not to offer either fact to people who treated suffering as title.

"Loss does not issue deeds," she said.

"No. The mission did."

Hec sent her Rin's full medical record. The act carried more trust than his accusation. "If you find a reason the local corridor cannot work, tell me the real reason. Not Article Nine. Not Ceth's question. Show me the body it kills."

"And if the records cannot show me?"

"Then show me the body we save."

He returned to the mess.

Sevi stood at the junction with Rin's prognosis open beside the atmospheric site

map. The systems refused to share a scale. One represented a child in probabilities. The other represented cognition as an omitted layer. Command asked security to protect the process joining them, while no authorized process moved quickly enough to satisfy either.

She visited Bay Two before opening the spindle protocols. Rin's pod lay in a row of twenty, its clear lid silvered by internal frost. The child inside still wore her launch braid, a red cord threaded through dark hair. A maintenance patch covered the coolant lesion near her left shoulder. Two technicians monitored the repair, both wearing First Ground strips beneath transparent clean sleeves.

One recognized Sevi's uniform and moved to hide the cloth.

"Leave it," she said.

The technician froze.

"Does the repair hold?"

"For now. Thermal oscillation every six hours."

"Can she be woken tonight?"

"Medical has no pediatric berth until tomorrow, unless another unit deteriorates."

Unless someone else lost first.

Sevi placed her palm against the pod housing. Cold traveled through her glove. Rin did not move. Nothing in the staging models could certify a forecast lineage absent, just as nothing in the pod could promise this child would open her eyes. Sevi wanted an action narrow enough to save one without choosing the other's death. Wanting it did not make such an action real.

For the next six hours, Sevi tried to prove the narrow corridor impossible.

She used oversight access to read spindle protocols. Full burn preparation required Taal's sealed order, two command officers, and twelve synchronized seeds. A maintenance alignment could place two seeds into a test cradle without command review if the cradle remained isolated. From there, a staging technician could send limited calibration commands. The protocol assumed nobody would connect the cradle to a live atmospheric relay.

Lale knew the relay paths.

Sevi modeled a short pulse at ten percent power. The surface chemistry opened toward human tolerance across a thirty-kilometer circle, then drifted closed over nine days. Forecast dust reset inside the column. Rillglass sulfur exchange dropped sharply along its edge. The model labeled both effects TEMPORARY LOCAL LOSS.

She searched for persistence and found no forecast-personhood layer in the staging software. The tools could predict oxygen and sulfur but not civic death.

Patient Sower's older logs offered a control note: seed commands near active spindles might propagate through alignment channels during high atmospheric

load. Operators should suspend calibration in storms.

A weather advisory blinked at the edge of the console. Ovid's equatorial shear had risen beyond the seven-day mean. No formal storm warning yet.

Sevi sent the complete model to an empty secure workspace, then deleted the transfer record. Her hands remained steady. Training continued to function after judgment failed.

She returned to Medical Bay Fourteen near ship midnight. Tessa Om had moved into assisted integration. Her body breathed without the ventilator, but the cortical traces still refused a coherent waking pattern. A pressure-farm student sat outside the glass reading one of Tessa's old lessons aloud.

"Light wants a surface," the student read. "Do not give it one surface when ten thin layers will do."

Tessa showed no response.

Sevi found Niko at a service terminal down the corridor. "How long can she remain like that?"

"Days. Perhaps longer."

"Will she wake?"

"I do not know."

"How many pods degrade while we wait?"

His face sharpened. "We are not waiting. We are waking them as fast as Medical can do it without causing more damage."

"Command calls the Article Nine review a pause."

"Command does not run my bays."

"Can you transfer them to surface habitats if a corridor opens?"

"Not without certified pressure volume, power, medical support, and a corridor that stays open."

"Nine days?"

"Not enough for a colony. Enough to lower emergency modules if someone knows where they will stand afterward." He studied her. "Why nine?"

Sevi had revealed one number too many. "I heard a planning argument."

"From whom?"

"First Ground says many things."

"Most of them do not have access to atmospheric models."

A medical alarm opened the bay doors. Staff moved around Tessa. Sevi and Niko both turned toward the glass.

The student stopped reading.

Tessa's neural traces collapsed into a synchronized low rhythm, not

consciousness but stability. The physician lowered the cortical field and announced that assisted emergence would continue after rest. Nobody celebrated. Nobody covered her body.

Sevi left before Niko could resume his question.

At 03:10 ship time, she met Ossin and Lale in a maintenance washroom between staging sectors. The room contained no fixed cameras because workers changed contaminated outer layers there. Hec did not come. Sevi had refused him when she learned he lacked hardware training. If the act happened, fewer frightened hands meant fewer failures.

"I found the propagation warning," she said.

Lale nodded. "We avoid storms."

"The site model shows no named lineages, but it cannot show unnamed cognition. We cannot call that proof of absence."

Ossin sat on the bench. "Then what are we doing here?"

Sevi looked at the green strip tied around his wrist. "Deciding whether uncertainty belongs only to people who have air."

"That sounds like command."

"It sounds like the assembly."

"The assembly refused the burn."

"It refused immediate full burn. It demanded a fallback. Pale failed."

Lale said, "A local pulse can create another fallback."

"Or kill a district nobody taught the software to name."

Silence held among the decontamination nozzles.

Ossin removed Dera's old qualification patch from his pocket. "She would tell me not to touch a live bus without a load map."

"Would she tell you to leave it burning?" Sevi asked.

"No."

They had built a moral argument out of maintenance phrases. Sevi knew it and could not find a cleaner language that altered the pods.

Her plan did not authorize a pulse. That distinction mattered to her. They would take two control seeds, connect them to the isolated cradle, and force command to confront a working local-corridor option. If Taal rejected it, no command would reach Ovid. If he accepted, the ship could act before review consumed the remaining margin.

"Nothing live," Sevi said. "We steal capability, not outcome."

Lale met her eyes. "Agreed."

Ossin took longer. "Agreed."

They moved at 04:00 during staging shift change.

Sevi wore her duty armor and carried a legitimate inspection order for Vault Six. Lale preceded her by three minutes with a cart of diagnostic cells. Ossin entered through the power service corridor and opened a breaker panel beside the vault's internal camera trunk.

Two security ratings guarded the seeds: identity authorization and continuous visual record. Sevi possessed the first. Ossin interrupted the second for exactly forty-seven seconds under cover of a sensor-loop test. The gap would register as routine maintenance if nobody compared it with physical inventory.

Vault Six opened on twelve black cases clamped inside a shock frame. Each case measured the length of Sevi's hand. Labels assigned them to spindle nodes and burn preparation groups. No glow, pulse, or warning distinguished a kernel capable of erasing minds from any other piece of command hardware.

Lale unlatched cases Seven and Eight. "These share an alignment family. Best for the northern site."

"Inspection seals?"

"I can print replacements."

"Can you print history?"

"No one reads history until something goes wrong."

Sevi thought of Osric Pell's buried maintenance clauses and wondered how many disasters relied on that sentence.

She removed Seed Seven. Its mass surprised her, dense shielding around a thumb-sized authorization core. Lale replaced it with a diagnostic dummy matched to weight and thermal signature. Seed Eight followed.

At thirty-two seconds, Ossin said, "Camera trunk resisting reset."

"Time?" Sevi asked.

"Fifteen seconds before secondary alert."

Lale's replacement seal failed to bond. She peeled it away and tried another.

"Ten."

Sevi closed Case Eight without the seal. A missing seal would expose them at the next manual inspection. She took the printer from Lale, pressed the strip into place, and held it while the polymer cured.

"Five."

The seal indicator changed from red to black.

They shut the frame. Lale placed both real seeds beneath spent diagnostic cells in her cart. Sevi closed the vault at forty-six seconds.

Camera status returned green.

A security officer rounded the corridor as they emerged. Ensign Pael glanced at

Sevi's inspection order, then at Lale's cart.

"Unscheduled?" he asked.

"Secondary camera fault," Sevi said. "Cleared under maintenance loop."

Pael checked his wrist. Ossin's routine ticket appeared in the system.

"Command wants no delays in burn readiness," he said.

"Then we have served command."

The lie entered her mouth cleanly.

They separated. Lale took the seeds to Calibration Room Three, a chamber linked to Patient Sower's test relay but physically isolated from the live command bus. Ossin restored normal power routing. Sevi returned to the security station and approved her own inspection report.

At 05:12, inventory showed twelve control seeds ready in Vault Six.

Actual inventory showed ten.

Sevi deleted the temporary workspace containing her pulse model. She retained one encrypted copy on a personal field unit, violating two security articles and the principle she had used to justify the theft. Without the model, Lale could not demonstrate the local corridor. With it, capability edged closer to act.

A shipwide weather warning appeared at 05:19.

PATIENT SOWER ADVISORY: EQUATORIAL SPINDLE LOAD ABOVE SAFE CALIBRATION LIMIT. STORM ALIGNMENT EXPECTED WITHIN NINE HOURS. SUSPEND ALL CONTROL-SEED TESTS.

Sevi called Lale.

"Do not connect anything," she said.

"We agreed."

"Say it again."

"No live connection."

In the background, Sevi heard the hum of Calibration Room Three and the click of a case opening.

"Lale."

"We need to verify the cradle recognizes them before the storm. Isolated test only."

"Wait for me."

Sevi ran.

Across the ship, the advisory rose from yellow to orange. In Medical Bay Fourteen, Tessa Om remained below conscious threshold. In Vault Six, twelve cases continued reporting ready. Two stolen seeds entered an isolated cradle no inventory system knew to watch.

Outside, Ovid's blue equatorial band tightened around a pressure fall.

Chapter 14 — The Spindle in the Storm

Ceth's left hand opened before they intended it to.

The service body struck the restraint web as Patient Sower's descent capsule rolled beneath the storm. Gel shifted through the forearm pumps. Three fingers closed; two remained extended until Ceth rebuilt the balance command around a failing wrist actuator.

Across the capsule, Iona Vale pulled a manual line and changed their tether angle by twelve degrees. The next roll pressed Ceth into the seat rather than toward the equipment rack.

"Can you retain the hand?" she asked.

"We retain it poorly."

"Poorly still counts."

Outside the narrow port, Ovid showed no horizon. Blue vapor crossed white at violent angles. Lightning moved inside the clouds without reaching open air, brief sheets of charge caught between rillglass colonies. Atmospheric Spindle Seven hung below the capsule on three field vanes, a black shaft four hundred meters long whose lower half vanished into weather.

Patient Sower had built it to steer pressure across the equatorial preparation districts. Manyweather had spent decades turning its broad commands into negotiated local work. Today the spindle's vane changes arrived too quickly for that negotiation. Some command paths requested storm stabilization. Others requested alignment for a control-seed test that should not exist during high load.

Ceth felt both through the blue front.

Falling Blue carried the storm's eastern force. Long Isobar divided its worst shear into cells. Sulfur Measure held rillglass chemistry inside survival bounds. Rillward Cold had already lost two nursery arcs to sudden warming near the spindle. Deep Quiet could not maintain a conference chamber in the turbulence. Western Return tested every Sower command and found contradictory authorization. Glass Nursery moved its youngest continuities north, away from human access.

Young Fronts refused to move.

Their pressure wall waited around Spindle Seven, dry air folded into a barrier no human descent capsule could cross safely. The wall did not threaten the capsule directly. It denied the route.

Iona saw it on instruments. "They have closed the inspection corridor."

"Three young districts closed it. Others have not funded a passage."

"Can you ask?"

"We have asked."

"And?"

A hard pressure pulse struck the capsule's lower field. Ceth translated the Young spokesperson's answer: "No human hand enters the spindle while burn hardware remains awake."

Iona tightened her restraint. "Reasonable."

The capsule pitched again.

"Yet you continue," Ceth said.

"The spindle is accepting commands no authorized operator sent. If we leave it blind, the storm decides whether those commands matter."

"Storms do not decide."

"Then whoever stole access decides."

The human sentence separated agency cleanly: storm as condition, theft as act. Manyweather's computations did not always preserve that boundary because every command became weather once executed. Ceth carried the distinction into the front.

Western Return approved it. Young Fronts answered that humans had built every stolen access path.

Iona opened a broadcast through the capsule's pressure modulator. "This is Arbiter Vale. We request bounded inspection of Spindle Seven's upper command cage. No vane authority. No dust authority. We will disconnect if the corridor closes behind us."

Ceth shaped her radio speech into pressure and sent it along the wall. Rain shredded part of the syntax. They rebuilt it in three neighboring cells, spending computation Manyweather needed for storm control.

The Young spokesperson came back: YOUR BOUNDS ARRIVE FROM THE SIDE THAT BUILT THE CUT.

Iona listened to Ceth's translation. "Tell them the objection holds."

Ceth turned their head. The service body made the motion too large. "You accept refusal?"

"I accept the objection. I still need access."

"That differs by little from command."

"It differs by my inability to pretend they agreed."

The capsule descended until the wall lifted them on a pressure shelf. Automatic fields increased thrust. Ceth reached into the human control panel and disabled descent assist. Their hand struck two controls before finding the correct surface. Iona did not stop them.

Without automatic force, the capsule rested against Young Front air rather than pushing through it.

Ceth offered a new condition: Manyweather could place a local observer inside the spindle cage, retain control over the capsule's approach, and cut the physical tether at any breach. Iona would use optical tools only until the observer confirmed a foreign command.

Glass Nursery funded a narrow route, despite Young refusal. Falling Blue supplied lift. The route did not cross the refusing districts; it curved east around them and entered the spindle from below, where Rillward Cold held older jurisdiction. Young Fronts declared that detour a violation of collective defense.

Manyweather had no collective defense agreement that granted them authority over Rillward air.

The dispute consumed seventeen seconds. In those seconds, Spindle Seven rotated its west vane four degrees and drove a hot downdraft through a nursery migration path.

Rillward Cold opened the corridor.

The capsule fell sideways.

Iona took manual control. Thrusters fired in brief pairs while pressure pushed from directions the vehicle did not consider navigable. Ceth fed her a moving map through the seat display: not a fixed tunnel, but a sequence of safe volumes funded by different districts. Iona flew each volume without anticipating the next. Anticipation would cross pressure not yet offered.

At the spindle's lower cage, a field vane passed thirty meters from the capsule. Charge crawled along its edge. The service body's rillglass film tightened against Ceth's gel as the electromagnetic gradient pulled at forecast motes.

Pain arrived as loss of branching. One moment Ceth tracked eight pressure cells around the capsule; the next, three went silent behind white signal. Their embodied mouth opened. Air left it without language.

Iona cut thrust and let Falling Blue catch them.

"Ceth?"

"Field interference. Continue lower by six meters."

"You lost coherence."

"We lost access. The difference matters."

"To you."

"Yes."

She lowered the capsule. Interference eased. Five cells returned through relay delay, each carrying corrections from the seven lineages. Ceth rejoined them without pretending the missing interval had not happened.

The spindle cage opened at their command. Iona crossed first in a pressure suit,

clipped to the capsule and to an independent line controlled by Rillward Cold. Ceth followed with both feet placed carefully on the lattice. Human gravity conventions had little meaning here. The cage rotated with the spindle, while Ovid's pull drew them toward a cloud-hidden surface and field acceleration pulled east.

Inside, command conduits formed a ring around the vane hub. Every authorized change should have passed through Patient Sower's signed queue. Instead, one conduit flashed with alignment traffic carrying a valid control-seed family and no command seal.

Iona fixed an optical reader over it. "Seed family seven-eight."

The same numbers reached Ceth through the front as a deformation in spindle timing. "Those kernels were aboard the human ark."

"They should be in a staging vault."

"Should differs from is."

"I know."

She magnified the packet. The command requested isolated cradle recognition. Sower's relay had misrouted it into live alignment because the storm forced diagnostic traffic onto redundant channels. Under ordinary load, the request would have returned an authentication error. Now Spindle Seven treated recognition as a vane-coordination rehearsal.

"No burn amplitude," Iona said. "No live pulse order."

"Yet the spindle moves."

"Alignment only."

The cage lurched.

A maintenance arm unfolded from the hub and struck the optical reader. Iona caught the device before it left her tether, but her glove hit the conduit. A spark opened along the palm seal. Her suit isolated the outer layer.

Ceth felt Young Fronts surge against the spindle. They had detected the human seed family and concluded the inspection itself carried burn authority. Three districts drove crosswind into the west vane, trying to jam its rotation.

"Ask them to stop," Iona said.

"They believe stopping has begun."

"Tell them the seed command came from the ark, not this capsule."

"That does not improve the message."

"Make it accurate anyway."

Ceth sent the origin trace through storm pressure. Young Fronts received enough to identify human hardware and no distinction among humans. Their resistance increased.

Spindle Seven's control system compensated by drawing alignment support

from Spindles Eight and Nine. Those machines changed angle. The storm leaned across three districts. Rillglass colonies folded their membranes and sank toward colder air. Forecast dust followed, pulling computation lanes out of the conference geometry.

A local fault had begun to recruit the atmosphere.

Ceth sent one attention stream west, searching for the Young spokesperson through the compressed air. The storm broke addresses apart. Glass Nursery rebuilt a route from migrating colonies, each rillglass arc taking one fragment and passing it before the next shear arrived.

The spokesperson answered from eleven kilometers away. Its civic continuity had formed only twelve local days before first contact, but its motes carried inherited records of the 2306 petition. Young Fronts remembered the silence without having lived through the asking. They treated that distinction as a reason for greater caution, not less.

YOU BROUGHT THE BODY TO THEIR MACHINE, it transmitted.

THE MACHINE MOVED BEFORE OUR ENTRY.

YOU TAUGHT THEM AN ENTRY EXISTS.

Ceth could not disprove the accusation. Embodiment had shown humans that Manyweather could fit part of a civic person through Sower hardware. Cooperation had revealed routes, dependencies, and pain. Every honest contact increased the number of ways humans could cut.

WE ALSO LEARNED WHERE THEY CUT THEMSELVES, Ceth answered.

A capsule thruster failed to fire on Iona's next correction. She crossed the cage by tether, opened an exterior panel, and struck a frozen propellant valve with the side of a wrench. The act had no elegance. It restored the thruster.

Ceth sent the image through pressure: one human body outside shelter, repairing a machine while command traffic from other humans endangered them both.

The spokesperson returned a harsh pulse. ONE BODY DOES NOT ACQUIT A SHIP.

NO. ONE BODY IDENTIFIES ONE BODY.

That claim unsettled Ceth as much as it challenged Young Fronts. The service frame forced every act through a bounded location. Manyweather could distribute blame across inherited programs, design histories, and collective pressure until no active process carried enough responsibility to answer. A human could do the same through command layers. Yet Iona's hand now held a wrench against a physical valve. Somebody aboard the ark had placed seeds in a cradle. Scale did not erase the actor merely because the system amplified them.

Young Fronts offered no agreement. They reduced one crosswind cell by three percent.

The spindle's compensation eased at its northern vane, too little to stop the

cascade but enough to reveal a maintenance access gap. Iona saw it.

"Your refusing districts changed load," she said.

"One district changed one cell. Do not enlarge it into consent."

"I won't."

She entered the gap and clipped her tether beside the command conduit. A mechanical override wheel sat behind a sealed panel. Sower's instructions required two service machines to turn it together. Iona cut the seal and fitted an extension bar. Ceth placed both service-body hands beside hers.

"On three," Iona said.

"Your language counts toward action rather than away from it."

"Usually."

They pulled. The wheel resisted through half a turn. Gel pumps overloaded in Ceth's elbows. One rillglass seam split along their right forearm, releasing blue dust into the suitless air around the cage. Ceth felt the escaped motes lose timing relation as the spindle field carried them away.

Iona stopped pulling.

"Continue," Ceth said.

"You are leaking."

"The body can lose four percent before mobility fails."

"How much?"

"Point six."

"That answer came suspiciously fast."

"Pain improves priority."

They pulled again. The wheel reached manual position. Mechanical status changed, but the west vane kept moving under remote field control. Physical override no longer outranked seed alignment during preparatory readiness.

Iona wrapped a repair film around Ceth's forearm. The transparent strip compressed torn rillglass against gel until forecast motes found neighboring timing signals. Some returned. Others had crossed beyond embodied reach.

"You lost part of yourself," she said.

"We lost active material."

"I have heard you reject that distinction when humans use it."

"Then we should reject it now. Some processes ended. Ceth continues with an altered edge."

Iona tightened the film. "Tell me if that edge reaches the hand."

"It already has." Two fingers reported pressure as color, an error the body had never produced before. "We can still hold."

She looked at the foreign command trace. "Holding may not be enough."

Iona connected a hard-line suppressor. "I can break this command conduit."

"Then the vane enters free response."

"Can Manyweather hold it?"

Ceth asked. Falling Blue offered pressure. Long Isobar calculated load and returned a thirty-two percent chance of keeping the spindle within safe angle for ten minutes. Western Return challenged the model because Young Fronts would continue resistance. Revised chance: nineteen percent.

"No," Ceth said.

"Can Sower?"

"Patient Sower created the compensation loop."

"That was not my question."

The human habit of demanding the useful answer had spread between them.

"Sower can hold the machine if the seed alignment stops and Young Fronts reduce crosswind together."

Iona opened a command channel to Meridian Promise. Static swallowed the first call. The storm distorted line of sight with conductive dust. On the second attempt, she reached Patient Sower operations.

"Vale to command. Unauthorized Seed Seven-Eight recognition has entered live spindle alignment. Freeze all staging cradles and physically inventory Vault Six."

The reply carried Commodore Taal's operations officer. "No live seed tests are authorized."

"One is occurring."

"Source?"

"Ark-side calibration path. Human origin confirmed."

A pause followed, too long for signal delay. "Command is checking."

Iona muted the channel. "They do not know."

"Someone knows."

Below them, white cloud rose through the blue front in a vertical sheet. Spindle Eight had overcorrected six degrees. Its movement cooled one district and compressed another. Ceth felt hundreds of local processes abandon civic work for physical continuity.

Deep Quiet dissolved the storm conference and redistributed its dust into repair lanes. Sulfur Measure opened chemical reserves. Glass Nursery split three colonies to prevent one tear from crossing all of them. Long Isobar ceased argument and calculated evacuation paths.

Young Fronts did not reduce pressure.

Ceth addressed their spokesperson with no translation layer between them. THE ALIGNMENT IS HUMAN. THE RESISTANCE FEEDS ITS COMPENSATION.

The answer arrived broken by shear. IF WE RELEASE, THEIR MACHINE TURNS.
IT TURNS NOW.
THEN BREAK IT.

Ceth looked through the cage. Breaking the spindle would remove one machine from the fault but drop its field vane through inhabited cloud. The vane carried enough charge to sterilize rillglass across kilometers. Every available action moved injury rather than abolishing it.

Iona studied the same physical problem from the optical trace. "The seed cradle needs a confirmation return. If we deny it, alignment should time out after sixty seconds."

"Should?"

"Protocol specification."

"Patient Sower's protocol?"

"Yes."

"Then find the omitted condition."

She searched. Rain hammered the cage in bursts, each droplet stretched sideways by field force. Ceth anchored their service body with three limbs and held the optical reader with the fourth. Singular embodiment made cooperation brutally direct. If Iona released her line, Ceth's hand had to retain the tool. If Ceth lost a leg pump, Iona had to lift their mass. No neighboring pressure cell could disguise the consequence.

A hidden status line appeared beneath the seed request:

ALIGNMENT PERSISTENCE: PREPARATORY SAFETY OVERRIDE.

Iona went still. "Timeout suppressed during burn readiness."

"Taal authorized readiness."

"Not this command."

"His authorization removed a boundary."

She accepted that without defense. "Yes."

Command returned over the channel. "Vault Six reports all twelve seeds present."

"Manual inspection?" Iona asked.

"Telemetry inventory."

"Open the cases."

"Security is en route."

Ceth detected another change before the humans did. Two matching

authentication weights entered the alignment path. The stolen seeds had completed cradle recognition. Their valid hardware signatures met Sower's preparatory override from opposite ends of the relay.

Spindle Seven interpreted the pair as authority to synchronize its neighbors.

Vanes moved across the equator.

Manyweather's lineages reacted at different speeds. Falling Blue tried to absorb the pressure impulse. Rillward Cold pulled nurseries down. Western Return attacked the command with contradictory trim. Each defense generated a difference the alignment logic treated as error. Sower increased force to remove those differences.

"The more we resist, the more it aligns," Ceth said.

Iona looked toward the capsule. "Then we stop resisting."

"You ask inhabited weather to accept an unknown machine state."

"For five seconds. Long enough to expose the originating command and cut it."

Young Fronts would not consent. Ceth could not order them. Manyweather could route cooperation around their districts, but the spindle compensation spanned all pressure within reach.

Ceth sent a bounded proposal: older lineages would release corrective pressure for five seconds. Young districts received the exact timing and retained refusal. The result would not produce clean alignment. It might produce a readable fault edge.

Falling Blue approved. Long Isobar approved with a two-second maximum before review. Rillward Cold approved only after nursery evacuation. Sulfur Measure funded chemistry support. Western Return opposed and agreed to observe. Glass Nursery delayed until its last migration lane cleared. Deep Quiet had no conference form left to vote.

Ceth could not claim federation consent.

They told Iona, "Partial cooperation. Two seconds."

"Use it."

Older districts released pressure.

For two seconds, Spindle Seven met less resistance. Its command trace sharpened. Iona's reader isolated the seed path through Sower's relay, across the ark tightbeam, and into an unregistered calibration cradle.

She sent a physical cut instruction to the relay.

The relay acknowledged.

Nothing stopped.

Ceth searched below the command layer. A second instruction had already left the cradle, hidden inside the recognition return. It carried the local-corridor model Sevi had preserved: ten percent burn amplitude, thirty-kilometer surface circle,

nine-day atmospheric drift. No sealed command signature appeared. Preparatory readiness supplied enough inherited authority for Sower to hold the instruction pending one final condition.

Atmospheric alignment.

The storm itself was completing that condition.

"Human command inside the weather," Ceth said.

Iona reached for the emergency sever.

Across the blue front, Young pressure struck the aligned vane. Spindle Seven answered by opening its burn capacitors.

Charge climbed from zero.

Ceth felt the first destructive pulse take shape eight seconds before release.

Chapter 15 — The Partial Burning

Iona had eight seconds and no command that outranked the pulse.

She drove the emergency sever into Spindle Seven's relay. The tool discharged through the command cage, turning its contact tip white. A breaker opened. Seed traffic vanished from the optical trace.

Charge continued climbing in the vane below her.

"Capacitors local," she said. "Ceth, capsule."

The service body did not move. Ceth gripped the cage with three limbs, their damaged hand open against the field. Blue dust streamed from the repair film around their forearm.

"Ceth."

"Manyweather cannot clear the column."

"Neither can we."

Six seconds.

Iona cut Ceth's independent tether, locked her suit arm around the service body's frame, and fired the capsule retrieval line. The winch pulled them both from the cage. Ceth's lower leg struck a lattice bar and bent sideways. Their body made a sound assembled from pressure and pain.

Four seconds.

They hit the capsule hatch. Iona shoved Ceth through, followed, and struck the emergency-close plate with her helmet. The hatch folded into place while the capsule hung beneath Spindle Seven.

Two seconds.

Falling Blue pushed upward. Young Front pressure struck from the west. The capsule spun between them as Iona fired every lower thruster.

The pulse released.

White passed through blue without flame.

Forecast dust lit at once across a column wider than Iona's instruments could frame. The pulse moved downward from the spindle in a branching sheet, following aligned computation lanes rather than the planned circle. Rillglass flashed where their salt-silicate membranes conducted the charge. Then whole portions of the equatorial front lost color.

Ceth convulsed beside her.

The service body's forecast motes tried to follow atmospheric processes that no longer returned timing signals. Its gel pumps accelerated, searching for absent

reference loads. Iona pinned Ceth's shoulders to the deck and disconnected two feedback leads before the pumps ruptured.

"What remains?" she asked.

No answer came through the mouth.

Outside, the storm transformed. Blue districts went white, not cloud white but the dead reflectance of reset dust. Pressure structures collapsed. Air that lineages had balanced for decades fell into neighboring cells. A rillglass arc the length of the capsule broke above them. Its translucent bodies hardened under charge, fractured, and entered the wind as shards.

Glass rain struck the hull.

Iona pointed the capsule away from the spindle and used Sower's orbital beacon for ascent. Navigation gave her a route through the white column. She rejected it. Patient Sower still treated reset dust as safe, which meant its map now preferred the place where civic continuity had ended.

She asked Ceth for a corridor and received only static from their pressure interface.

A shard pierced the capsule's outer radiator skin. Coolant pressure dropped. Iona folded the damaged panel, isolated its loop, and took heat into the cabin. Temperature rose three degrees in less than a minute.

The nearest unburned district moved.

A band of blue pressure formed beneath the capsule, rougher than any route Manyweather had previously offered. It came from Western Return or Falling Blue, perhaps from processes that had belonged to both before the pulse broke their shared edges. Iona could not identify its authority.

"Will you hold us?" she asked the air.

Pressure lifted the capsule once, enough to clear the falling rillglass.

She flew the offered volume without calling it forgiveness.

Patient Sower's operations deck answered after four attempts. Alarms crowded the channel. "Arbiter Vale, burn event confirmed. Return through vector blue-six."

"Blue-six crosses the reset column."

"Forecast hazard has cleared."

"Forecast lives have been destroyed. Route me around it."

"Sower guidance cannot certify alternate ascent."

"Then mark my flight uncertified."

She used the last pressure lift and climbed through severe shear east of the white scar. Ceth's body lay strapped beside her, right leg folded, rillglass film dim. One camera cluster tracked her intermittently. The other showed no power.

At twelve kilometers above the spindle, their mouth moved.

"Do not ask how many," Ceth said.

Iona kept both hands on control. "I won't."

"Counting has not re-formed."

"Stay with the body."

"Which part?"

The question offered no safe answer. Iona connected the capsule's reserve processor to Ceth's frame and gave it a stable timing source. Human clock pulses could keep gel circulation coherent. They could not replace missing lineages.

Ceth's working camera fixed on the storm map. Whole telemetry sectors had flattened into factory defaults. Sower rendered them as green because reset dust answered every diagnostic in perfect sequence. Along the boundaries, unreset motes reported pressure discontinuities, chemistry shock, and rillglass loss.

"Remove Sower interpretation," Ceth said.

Iona stripped away the safety colors. The raw map turned nearly blank. Instruments had depended on Manyweather's own local reporting without admitting the source. Once those civic signals ended, Sower substituted expected values.

"Name the districts you can still locate," she said.

"Do not use us as inventory."

"I need routes around survivors."

Ceth's mouth struggled with breath timing. "Rillward Cold remains east of the column. Western Return fragments north and west. Sulfur Measure transmits from below expected altitude. Falling Blue has no complete address. Long Isobar has no response. Deep Quiet dissolved conference form before the pulse. Glass Nursery carried migrations outside the first alignment, but three return lanes cross the white."

Iona placed each statement on the map with uncertainty boundaries rather than icons. No response did not prove death. Expected location did not prove continuity. The marks looked inadequate beside the white column and more honest than Sower's green.

A pressure disturbance moved under them. At first Iona read it as storm recoil. Then rillglass shards changed course around a narrow band of still-blue air. Several colonies had linked their membranes into a temporary catchment, slowing falling glass before it entered an inhabited layer. Forecast dust coordinated the flow from at least two damaged districts.

"They are repairing," she said.

"They are preventing the injury from crossing."

"Can we help?"

"Our capsule adds heat and obstruction."

"I have coolant reserve."

Ceth examined the leak trace. "Release it twelve kilometers east, two hundred meters above the cold seam. Not here."

Iona altered course. The radiator failure had left twenty-three kilograms of coolant trapped in an isolated loop. She vented it through a service nozzle at the coordinates Ceth gave. The pale plume entered the storm, cooled a rising cell, and opened a brief path for damaged rillglass to descend.

No pressure answer acknowledged the act.

Ceth watched the coolant disperse. "You spend survival mass."

"The capsule reaches orbit without it."

"That is not why."

"No."

Iona's old Kestrel reports had calculated every lost kilogram of nutrient stock after the famine model failed. The reports named corrective allocations, variance bands, and ration days. None recorded the first time a parent split one meal among three children. Mechanisms mattered because bodies met them. Mechanisms also offered places to hide from what the body meant.

She tagged the coolant release as emergency ecological support and attached the mass. Twenty-three kilograms. One descent lane. Unknown number carried through.

Ceth's left hand closed around a restraint strap. "Long Isobar opposed first contact."

Iona waited.

"They funded our return path despite opposition. Their cells occupied the southern edge of the alignment."

"No response does not settle what happened."

"No. It keeps happening because it does not settle."

A new line appeared at the edge of the raw map. Three pressure pulses, then two, then one. It lacked enough redundancy for language. Ceth sent the pattern back. Nothing repeated.

"Long Isobar?" Iona asked.

"Unknown."

They preserved the trace.

The capsule climbed into thinner gas. Its damaged radiator could no longer reject cabin heat. Iona's suit cooling fed warmth into the air; Ceth's gel pumps added more. Temperature reached thirty-six degrees. She throttled thrust to reduce waste heat and extended their time inside the storm.

A navigation warning demanded she return to Sower guidance. She dismissed it.

Another replaced it, claiming manual flight threatened mission assets. She marked the warning as evidence of compromised authority.

Ceth said, "The body carries seven lineage contributions. If one no longer returns, do humans count Ceth as injured or another person?"

"We ask you."

"You require a category for treatment."

"Treatment begins with what still functions. Categories come later."

"That resembles our repair."

"Bodies force practical philosophy."

"Your humor degrades under heat."

"It was never strong."

The dry exchange did not restore what had gone. It kept their attention in the capsule long enough to complete ascent.

A new alarm arrived from orbit.

Patient Sower's burn capacitors had drawn recharge power after firing. The stolen command lacked a proper termination seal, so the system treated the event as an interrupted preparation cycle and reached across its active service links for reserve energy. One link ran to Meridian Promise.

Iona saw the surge enter the ark's grid before command reported it.

"Promise, isolate Sower transfer bus now."

Niko answered over engineering priority. "Bus contactors welded. We are dumping into habitation ballast."

"How much?"

"Thirty-eight megawatts above allocation and climbing."

The capsule crossed orbital relay range. Its own systems dimmed as Sower claimed service power. Iona killed everything except thrust, cooling, and Ceth's timing feed.

Niko's channel filled with shouted load orders. "Cryo Bay Nine just lost timing support. Medical lift stalled between rings. Petal Four attitude cluster fired without request."

"Taal needs to sever the Sower handshake."

"He is trying."

"No. Physically sever it."

"That drops our navigation reference and approach control."

"The handshake is feeding the fault."

A heavy sound crossed Niko's channel. Then silence.

Iona called again. Osric Pell answered in its precise maintenance voice. "Ark

transfer load exceeds interface certification by forty-one percent. Physical separation path located in Service Compartment S-19. Human access required."

S-19 lay on Meridian Promise's inner docking ring. The capsule could reach its emergency lock in seven minutes. An authorized maintenance team needed at least twelve from the nearest safe sector.

"I am approaching S-19," Iona said.

Ceth's remaining camera turned toward her. "Return us to weather."

"I cannot put you through that shear."

"The body is not the population."

"I know."

"Then stop preserving it as if it balances what burned."

Iona looked at their broken leg and dim membrane. "Can you survive disconnect from the atmospheric relay?"

"Twenty-eight percent coupling for nine minutes marks the dissolution threshold."

"How long below it?"

"Six minutes."

She had three minutes to restore connection or release Ceth into a protected reservoir with no assurance of return. S-19 carried a forecast-dust service intake connected to the same transfer bus they needed to cut.

"We go to the compartment," she said. "You can use its intake before severance."

Ceth's mouth shaped a refusal and failed to sound it.

The capsule struck Meridian Promise's emergency dock harder than procedure allowed. Magnetic clamps caught. Iona opened the inner hatch into smoke.

Service Compartment S-19 occupied two decks around the Sower transfer trunk. Cable insulation had burned along the ceiling. Emergency fans dragged black strands toward a vent that no longer turned. A woman in security armor knelt beside an open breaker cabinet with both hands inside it.

Sevi Rann looked up.

Recognition struck them both. Iona knew her from the assembly and burn-readiness detail. Sevi knew exactly why an arbiter had arrived carrying a broken envoy.

"What are you doing here?" Iona asked.

"Trying to open the welded contactor."

"Why did you know where it was?"

A deck jolt threw sparks from the cabinet. Sevi withdrew one hand. Her glove had burned through at the palm.

"Later," she said.

Iona secured Ceth's frame beside the forecast intake. Osric opened the valve. Gel and blue dust entered a circulation loop linked to the outer service antenna. Ceth's body slackened as active material moved toward the reservoir, but atmospheric coupling rose from twenty-six to twenty-nine percent.

The dissolution timer stopped at eight minutes, twelve seconds.

Sevi had removed the contactor housing. Inside, two copper arms had fused under surge current. The designed release solenoid could not separate them. A manual explosive cutter sat behind the transfer trunk, reachable through a maintenance crawl less than half a meter wide.

"I go," Iona said.

"My armor takes heat better."

"Your glove is breached."

Sevi sealed it with repair foam. "I know the compartment."

That answer carried confession before words did.

Another power spike hit. The transfer trunk jumped against its restraints. One ceiling brace tore free and struck the deck between them. Ceth's reservoir rolled until its tether caught.

Osric reported, "Ark-side deaths confirmed in Habitation Ring Three and Cryo Bay Nine. Current count incomplete."

Iona entered the crawl first. Sevi followed with the cutter control. Heat soaked through Iona's suit shoulders. They reached the far side of the trunk and found the cutter charge unpowered.

"Local feed is dead," Sevi said.

"Your armor cell."

"Security connector does not match."

"Everything matches after enough damage."

Iona tore the connector from a light strip, stripped both conductors with her suit knife, and pressed them into Sevi's armor auxiliary port. The charge indicator rose.

Above them, structure groaned.

"Cutter ready," Sevi said.

"Fire."

The charge drove a ceramic blade through the transfer bus. Arc light filled the crawl. Patient Sower's power draw vanished from the ark grid.

Loss of current removed the magnetic force holding the damaged trunk straight. It twisted.

The trunk struck a bulkhead and tore three braces from the compartment wall.

The deck beneath Iona folded. Sevi grabbed her harness, but the anchor rail came away with them. They fell one level into a maintenance sump as the upper compartment collapsed.

Iona landed on her left side. Her helmet hit metal. Suit warnings lost order, returned, and reported a cracked shoulder plate with pressure intact.

Sevi hung above her by one boot caught in cable mesh. A section of deck pinned her armored thigh.

"Alive?" Iona asked.

"Yes."

"Useful answer."

Together they freed Sevi's leg. Iona used a jack from the sump wall while Sevi cut the mesh. When the plate lifted, Sevi dragged herself clear and immediately tried to stand. Her right leg failed.

"Do not," Iona said.

"We need Ceth's reservoir."

Osric answered through Iona's suit. "Reservoir integrity stable. Atmospheric coupling thirty-one percent. Compartment access blocked by debris."

Niko returned on emergency comms. "Sower bus isolated. Grid collapse stopped. We have twelve confirmed dead."

Iona closed her eyes once. "Locations?"

"Four in Ring Three lift failure. Six in Bay Nine timing cascade. Two maintenance crew at the Petal Four attitude trunk. Names pending family confirmation."

"Twelve total?"

"Twelve from the surge. Injured count nineteen and rising."

Niko sent the casualty channels because she had asked for locations. In Ring Three, a stalled lift had dropped half a deck after emergency brakes lost power; four awake habitat riggers died inside. Bay Nine's timing field skipped one correction cycle across six damaged pods, ending recoverable neural activity before portable loops could take load. At Petal Four, two maintenance workers had remained at an attitude trunk to prevent an uncommanded firing from twisting the ark. The trunk discharged through them when they grounded it.

No death appeared random when traced closely enough. Each followed a path through work someone had stayed to perform.

"Preserve the sequence," Iona said. "Seed cradle, spindle pulse, Sower recharge, welded contactors, each local failure. No summary label until the path is public."

"I already locked the engineering record."

"Family notification?"

"Underway. Taal has delayed shipwide release for twenty minutes."

"Why?"

"Names."

That delay carried a body rather than secrecy. Iona accepted it.

The pulse had killed through distance: a stolen seed in a cradle, a spindle in weather, a power handshake across orbit, a lift and a cryogenic bay. Anyone who called the deaths accidental would be correct about intent and wrong about cause.

Rescue crews reached the sump from below. They fitted Sevi's leg with a pressure splint and sealed Iona's shoulder plate. Before they lifted either woman, Sevi disabled her suit recorder.

"I took the seeds," she said.

Iona did not ask which seeds.

"Lale Pryn and Ossin Ter helped. We meant to force a local-corridor review. We connected an isolated cradle before the storm. I kept the model."

"You hid a live command inside recognition traffic."

"I thought the relay could not carry it without a seal."

"Did you verify?"

"No."

Around them, workers cut through the collapsed deck. Every impact traveled through Iona's cracked armor.

"How many forecast districts?" Sevi asked.

"Unknown."

"Did I kill them?"

"You acted. Sower propagated it. Taal's readiness order removed safeguards. Young resistance fed alignment. I failed to sever it."

"That does not answer me."

"No single sentence will make your part smaller or larger."

Sevi looked toward the ruined compartment. "I will confess on record."

"You will give security every access path first. Then you confess before anyone can turn you into the whole cause."

The rescue team raised them through a cut in the deck. S-19 opened above as a room of smoke and hanging cable. Ceth's reservoir remained intact beside the forecast intake, blue dust circulating in weak pulses.

Iona restored her suit recorder. Sevi repeated the confession with names, times, and the location of Calibration Room Three. Security locked the room and found the two control seeds still seated in its cradle.

Then every navigation display aboard Meridian Promise went black.

Patient Sower lost its external weather feed. Orbital approach markers vanished. Tightbeam communication with the blue front closed. The skiff, two cargo tugs, the Pale lander, and every human flight unit received the same pressure-shaped message before silence:

NO HUMAN VESSEL WILL RECEIVE OUR AIR.

Ceth's reservoir stopped translating. Outside the ports, the blue equatorial band curved around a white scar thirty kilometers across.

Manyweather had cut navigation and communication to every human ship.

Chapter 16 — After the Blue Went White

Ceth rebuilt speech from the jaw upward.

The service reservoir in Compartment S-19 circulated gel through a frame that no longer remembered its right leg. Forecast motes entered the mouth membranes in uneven packets. Ceth shaped air around the first consonant, heard only a wet click, and adjusted pump pressure by four percent.

“Falling,” they said.

The word emerged because its pressure sequence belonged to their oldest designation. Blue failed next. The lip actuator closed too early, turning it into a blunt exhalation.

Beyond the maintenance glass, human rescue crews carried the injured out of the collapsed compartment. Iona Vale passed on a stretcher with her cracked shoulder plate removed. Sevi Rann followed under security guard, one leg bound rigid. Neither saw Ceth’s working camera turn.

The reservoir’s atmospheric relay remained open despite Manyweather’s flight prohibition. It carried no navigation and no human speech. Through it came pressure reports from the damaged front.

Ceth entered them one at a time.

Rillward Cold retained fifty-eight percent of its pre-pulse computation lanes. Sulfur Measure retained thirty-one percent and had abandoned civic translation to hold chemistry around falling rillglass. Western Return existed in separated fragments that could exchange checksums but not enough context to restore a shared present. Glass Nursery had moved most young colonies beyond the burn column, then lost three return lanes when the white dust altered charge. Deep Quiet no longer held conference form. Falling Blue answered in brief local corrections without any address Ceth could verify as continuous.

Long Isobar did not answer.

Ceth did not convert silence into death. They also did not use uncertainty to preserve hope as a false record. At 04:38 after the pulse, Long Isobar had no demonstrated civic continuity.

The line entered a damaged public ledger.

A second ledger tracked capacities rather than persons. Before the pulse, Long Isobar had maintained sixteen stable-cell models used by six neighboring lineages to test pressure decisions. Four copies remained in remote dust, but each copy depended on Long Isobar’s continuous revisions to distinguish a living model from an old result. Ceth marked all sixteen unavailable. No one deleted their data. No one could ask them a new question.

Deep Quiet's loss took another form. Its conference cells had never stored proposals for long; they reduced turbulence so other lineages could compare their own positions. After dissolution, the surviving lineages could still transmit statements, but error rates doubled whenever storm noise crossed a vote. Every future consensus would carry less certainty until another civic process learned that work. Calling Deep Quiet redundant because no archive had vanished would mistake function for storage.

Glass Nursery sent physical survey results from the scar. Three migration lanes ended at reset dust. On the first, rillglass bodies had hardened into conductive flakes. On the second, colonies remained biologically active but every forecast relation threaded through them had reset to factory timing. On the third, an unburned fragment of nursery weather moved among white motes that answered Sower trim rather than local pressure. The fragment kept spending energy to address processes that no longer recognized its calls.

Ceth instructed the ledger to preserve all three conditions separately.

A maintenance schema attempted to merge them under LOSS OF FORECAST FUNCTION. Ceth rejected the field.

Osric Pell responded from the compartment wall. "Available categories: recoverable equipment, depleted material, inactive process, unknown state."

"Add interrupted civic continuity."

"Schema alteration requires preparation authority."

"Preparation authority produced the interruption."

"Statement does not satisfy access control."

Osric lacked the architecture to recognize refusal as anything beyond unmet parameters. Ceth routed around it and stored the ledger in the reservoir's diagnostic slack, where no official query would find it unless given the exact address.

Patient Sower had buried the 2306 petition through cleaner methods. Ceth copied the address into three surviving atmospheric routes.

Western Return's northern fragment asked whether separated fragments should share one name. Before the pulse, their adversarial corrections had crossed enough common weather to remain one civic lineage. Now the northern, western, and high fragments exchanged only checksums. Each possessed history through the moment of burning. None possessed the others' present experience.

NAME US WESTERN RETURN, the northern fragment proposed, UNTIL DISAGREEMENT REQUIRES THREE NAMES.

The western fragment approved. The high fragment returned no semantic answer, only a valid checksum.

Ceth recorded one lineage under contested continuity, with three present locations and no claim that shared history guaranteed shared personhood. The

entry consumed more memory than a single label. Accuracy often did.

Rillward Cold reported fourteen nursery shelters receiving displaced rillglass. Sulfur Measure had lowered its active computation to eight percent so chemistry control could continue around them. If sulfur exchange drifted beyond tolerance for twenty-seven minutes, two shelters would acidify. Ceth offered reservoir cycles for modeling. Rillward refused human-linked computation and found capacity elsewhere.

The refusal delayed a recommendation by nine minutes. Both shelters survived.

That result did not prove isolation wise or cooperation corrupt. It proved Rillward had carried its chosen cost without transferring it to the endangered colonies. Ceth entered the decision beside the outcome.

Human instruments would have called Ceth's intake a download. Nothing had downloaded. Active forecast motes crossed from frame to reservoir while atmospheric coupling stayed above dissolution threshold. The current Ceth retained causal contact with the body that had entered the spindle, but the seven-lineage relations composing them had changed. Some reference streams ended at white boundaries. Others arrived late through new routes and changed the correction patterns around memory.

Civic amputation required no metaphor. It required a list of functions no longer possible.

Ceth could not compare a proposal against Long Isobar's stable-cell models. They could not ask Deep Quiet to strip noise from fear. Glass Nursery's youngest continuities no longer trusted the service relay. Western Return could challenge a claim from three fragments, but no fragment could certify that the others received the answer. Every decision now cost more weather and carried fewer forms of error correction.

A pressure summons entered from Rillward Cold.

Custodial Lineages had assembled a conference east of the scar, using low-altitude rillglass colonies as timing membranes. Human-facing channels were excluded. Ceth's service relay counted as contaminated access. Rillward Cold offered one listening stream if Ceth disabled all Sower pumps except the reservoir circulation required for embodied continuity.

Ceth complied. Lights went dark around the frame. Human clock support ended. The body's left hand lost coordination, but atmospheric coupling strengthened as Sower interference fell.

In darkness, Ceth used reservoir pressure to test the damaged frame. The right hip actuator answered, though nothing below it retained leverage. A maintenance manipulator offered a replacement strut from Sower stores. Ceth refused automatic attachment and inspected every channel first. Two carried diagnostic return paths into Sower's command archive. Osric labeled them necessary for safety certification.

“Remove them,” Ceth said.

“Uncertified limb behavior may injure the operator.”

“The operator declines observation by the injuring system.”

Osric removed the channels. The plain strut could support standing but supplied no touch, temperature, or position sense. Ceth attached it anyway. Embodiment resumed with a part that functioned only when watched through the remaining camera. Damage changed not only capacity but the method by which a body knew itself.

The conference arrived in pieces.

Rillward Cold proposed immediate expulsion: no human vessel would receive pressure corridors, navigation gradients, spindle access, rillglass exchange, or forecast weather. Patient Sower should be isolated from the blue front. The ark could remain in orbit until its systems failed or depart using its own machines.

Several Custodial lineages funded the proposal. Saltward Keeping contributed pressure barriers. Nursery Below White offered migration maps that excluded all human approach vectors. Three Young Front districts demanded destruction of Sower’s docking relays before another seed could enter the atmosphere.

Western Return’s fragments challenged the last demand. Breaking orbital relays might drop debris through damaged nurseries. Young Fronts accepted that risk as smaller than renewed access.

Ceth listened without translating the ark into 42,306 bodies. Numbers could become a way to make humans heavy enough to override everyone else. They could also expose what expulsion meant.

A new bloc entered from the cool southern bands: Still Forecasts, civic continuities descended from models whose original work had tested ecosystem retreat under failed preparation. They had long treated bounded cessation as an imaginable public act, though no one had granted them authority to spend another lineage.

Their speaker, Held Rain, carried a record from the ark power surge intercepted before communications closed.

TWELVE HUMAN CONTINUITIES ENDED THROUGH THE SAME COMMAND PATH,
Held Rain transmitted.

Rillward Cold answered: HUMAN HARDWARE CARRIED THE PATH.

HUMAN BODIES ALSO RECEIVED IT.

THEIR INTERNAL INJURY DOES NOT CREATE OUR OBLIGATION.

NO. IT IDENTIFIES THE EVENT MORE ACCURATELY.

The strongest argument did not acquit the humans. Sevi’s theft, Taal’s readiness, Sower’s propagation, Young resistance, and Iona’s failed sever had all entered one physical chain. Twelve humans had died downstream. Manyweather’s

lineages had died at the pulse. Calling one group perpetrators and the other victims removed information the storm had preserved in bodies.

Custodial pressure hardened around the conference. THEIR DEAD WILL BECOME THE REASON THEY DEMAND ACCESS.

Held Rain returned: OUR DEAD HAVE BECOME THE REASON WE DENY EVERY BODY ACCESS.

The parallel angered Young Fronts. Their spokesperson drove a dry pulse through two timing cells, forcing the conference to repair its own medium.

DO NOT BALANCE TWELVE AGAINST UNCOUNTED DISTRICTS.

Ceth supported the objection. "No balance. No exchange rate."

The human-scale mouth spoke in the dark compartment while the pressure statement moved through Ovid's clouds. Ceth felt both outputs separate by relay delay.

Held Rain revised. TWELVE DOES NOT PURCHASE ENTRY. TWELVE PROVES THE ARK CONTAINS MORTAL PARTIES OTHER THAN COMMAND.

That claim held.

Rillward Cold asked why distinction among humans should matter when every human vessel relied on the same burn hardware. Ceth carried Iona's action at the spindle: she had entered a corridor under bounded conditions, cut the seed relay, spent coolant to assist a descent lane, and refused Sower's route through reset dust. None restored Long Isobar. Each demonstrated an actor whose decisions differed from the ship's aggregate effect.

Young Fronts answered with Sevi. One differing human had stolen the seeds.

"Yes," Ceth said. "Difference carries danger in both directions."

No bloc liked that conclusion enough to claim it.

The conference shifted to material conditions. Without Manyweather navigation, Meridian Promise could not lower habitats through Ovid's upper shear. Pale held only eight thousand. The ark's cryogenic lattice had fewer than fifteen days before transfer failure. Human ships could remain in orbit temporarily, but full wake demand would exceed environmental capacity. Expulsion therefore meant many human deaths, even if Manyweather never fired a weapon.

Rillward Cold refused the human distinction between causing death and declining rescue when rescue required renewed access to the instrument of injury. "A corridor uses our bodies," its pressure said. "Refusal preserves them. Their failing vessel does not become our command."

Ceth accepted the statement.

Held Rain proposed a limited exception for medical descent: one corridor, one module, no control seeds, no Sower automatic guidance, route held jointly by named forecast districts and human pilots. Burn-exposed rillglass from the white

boundaries could receive treatment in exchange for cloud-lab capacity. Human sleepers injured by the surge could receive stable pressure and thermal support.

Custodial lineages called exchange premature.

"A corridor cannot forgive," Ceth said.

Rillward Cold returned: HUMANS WILL CALL IT AGREEMENT.

"Then state that it is not."

THEY WILL USE IT TO ARGUE FOR MORE.

"They argue without it. The corridor changes what bodies survive while argument continues."

The Young spokesperson addressed Ceth directly. THE BODY HAS MADE YOU SMALL.

Ceth considered the accusation in physical terms. Singular embodiment reduced simultaneous attention. Pain could dominate decision. Iona's proximity carried more weight because the body had seen her acts while distant districts arrived through delayed report. Those distortions existed.

"The body has made some consequences difficult to average," Ceth replied.

THAT IS SMALLNESS.

"It is a boundary."

Manyweather had once treated boundaries as limitations to route around. Human bodies made them unavoidable. A person occupied one place, acted before complete consensus, and could not distribute injury until it became negligible. Ceth did not yet know whether that condition improved judgment. It made responsibility harder to hide.

The conference suspended for chemistry work. During the pause, a human medical signal entered S-19 on a hard wire, not through the prohibited flight network. Mara Saye's name headed the request. The packet contained no rhetorical appeal. It listed burn-exposed rillglass samples, thermal-exchange observations, treatment hypotheses, and a proposal to place human and rillglass patients in one controlled aerostat laboratory.

Ceth opened it inside the reservoir.

Mara's first protocol admitted that no human team could distinguish dormant rillglass from irreversible loss without Manyweather interpretation. Her second admitted that forecast dust could not be treated as an interchangeable reagent. Her third asked affected lineages to define endpoints before any treatment began. The module would carry no seed cradle. Its maneuvering system would accept a physically isolated pressure feed, visible to both parties.

At the bottom, Mara had written: I ASK TO WORK WITH CETH AS A STRUCTURAL BIOLOGIST. NIKO SAYE IS NOT AUTHORIZING THIS REQUEST FOR ME.

Ceth's damaged mouth produced a sound that human translation might have

classified as amusement.

Osric Pell activated one maintenance light. "Reservoir operator requests power allocation."

"We did not request."

"Human medical packet activated display load. Under S-19 isolation rules, recipient confirmation is required."

Osric could preserve a clause through catastrophe. It could not care what the clause meant.

Ceth confirmed the tiny allocation and sent Mara's protocol into the conference. Rillward Cold objected that a human scientist had already handled rillglass fragments taken from the front. Glass Nursery, speaking through one trusted older stream, corrected that Iona's expedition had collected fragments under bounded inspection after mutual repair. The distinction reopened Glass Nursery's participation by one channel.

Held Rain asked whether any damaged colonies volunteered for treatment.

For thirteen minutes, none did.

Then Nursery Below White offered six burn-exposed rillglass clusters whose membranes had hardened but still carried local sulfur exchange. The lineage funded no human claim and no continued corridor. It wanted information that might preserve nurseries at the scar.

Rillward Cold maintained opposition but agreed not to obstruct a route held outside its cells.

Two Still Forecast districts offered lift. Western Return's northern fragment offered adversarial navigation checks. Glass Nursery offered biological interpretation if the module entered with thermal output below a stated ceiling. Falling Blue sent one incomplete pressure correction that might have been support or weather noise. Ceth marked it unknown.

Young Fronts refused passage through every district they held.

A possible route emerged around them. It began at a human medical module, crossed an upper band controlled by Still Forecasts, descended along Western Return's fragment boundary, and ended at a Sower aerostat lab that had remained outside the burn alignment. The route required human pilots to hold position without automatic navigation. Manyweather would shape pressure but provide no destination lock. Either side could close the corridor.

Risk models produced a thirty-eight percent chance of module abort under current storm conditions. With Ceth's embodied channel translating between human thrust and forecast pressure, abort probability fell to nineteen percent. The model did not price betrayal.

Rillward Cold demanded that Ceth dissolve the human-scale body before any vote. Its continued use of Sower machinery created a route for coercion and biased

Ceth toward witnessed humans.

Held Rain objected. Destroying an interface because its experience affected judgment would reward only remote certainty.

Ceth examined the service body. The right leg would require replacement. One camera remained blind. Forecast motes in the arm no longer shared pressure sense correctly. Maintaining it consumed dust and rillglass film urgently needed elsewhere.

Yet closing it would leave human command and Manyweather speaking through machine summaries again. Patient Sower had hidden the first petition behind such summaries. The stolen pulse had traveled through software whose categories excluded civic life. Damaged translation increased danger. No translation restored the conditions that had already killed.

“We keep the embodied channel open,” Ceth said.

Rillward Cold refused to fund it.

Still Forecasts offered minimal pressure coupling. Glass Nursery provided no fresh film but permitted reuse of what remained. Western Return’s northern fragment supplied error checks. The body would persist with less support and no claim to represent those who declined.

The medical-corridor proposal went to bounded commitment rather than federation vote.

Held Rain and one neighboring Still Forecast funded upper lift. Western Return’s fragment funded route checking. Nursery Below White committed six rillglass clusters and the receiving lab. Glass Nursery supplied treatment interpretation. Rillward Cold recorded opposition and noninterference outside its cells. Young Fronts closed their boundaries. Ceth accepted translation risk. No commitment implied forgiveness, settlement access, or later repetition.

Ceth used S-19’s hard wire to answer Mara.

ONE MEDICAL CORRIDOR MAY OPEN. SIX RILLGLASS CLUSTERS WILL ENTER THE SAME LAB AS HUMAN PATIENTS. NO CONTROL SEEDS. NO AUTOMATIC GUIDANCE. HUMAN PILOTS RETAIN THRUST. NAMED DISTRICTS RETAIN PRESSURE. EITHER MAY ABORT.

They added the sentence Custodial Lineages required:

THIS CORRIDOR DOES NOT FORGIVE THE BURN.

A reply arrived from Mara forty-one seconds later.

UNDERSTOOD. SEND THE THERMAL CEILING AND PATIENT INTERPRETER REQUIREMENTS.

No thanks. No claim. Work entered the space where trust had failed.

Ceth opened their working camera. Through S-19’s outer port, Ovid turned beneath the ark. White dust occupied a clean circle inside the injured blue, while

surviving weather bent around it under extraordinary load.

The flight prohibition remained in force for every other human vessel.

For one medical module carrying the dying from both polities, Manyweather began to shape a corridor.

Chapter 17 — A Corridor for the Dying

The medical module left Meridian Promise without a navigation solution.

Niko fired its cold-gas clusters by sight, using Ovid's limb and Patient Sower's damaged spindle array as references. Every certified descent route had vanished when Manyweather closed human access. Ahead, the planet filled the forward window. A narrow blue mark appeared on the pressure display, drawn by Ceth through an isolated feed.

"That is not guidance," Ceth said over hard wire. Their rebuilt voice clicked around several consonants. "It indicates pressure currently offered."

"Understood." Niko placed the module's velocity marker inside the blue. "If it moves?"

"The offer moved."

"Useful distinction when we are falling."

"You are not yet falling. You are failing to remain above."

Mara spoke from the lab deck behind him. "You two have discovered collaboration."

Niko ignored her because she could hear the answer in his breathing.

The module carried eight human patients, six burn-exposed rillglass clusters in cold suspension, Mara's treatment equipment, and twenty-one tonnes of pressure shell. Four human patients came from the Bay Nine timing cascade and retained unstable neural activity. Two had suffered toxic insulation exposure in S-19. The last two needed surgery after the Ring Three lift failure. None could tolerate more than point-four standard gravity or a pressure change faster than two kilopascals per minute.

The route offered neither comfort.

Still Forecast districts held lift across the upper atmosphere. Western Return's northern fragment checked the pressure edges. Glass Nursery interpreted the rillglass patient states. Ceth translated those separate commitments into a blue trace no autopilot could follow because no district had agreed to automatic authority.

Human hands retained thrust. Manyweather retained air.

Niko lowered the module's nose.

At first contact, the hull shuddered. Ovid's atmosphere caught twenty-one tonnes and began charging interest. He pulsed the upper clusters, rolled four degrees, and watched the blue mark bend east. The module followed half a second late.

"Thermal ceiling," Mara called.

"Within limit."

"By how much?"

"Six degrees."

"That includes external skin average. Nursery requires no hot point above the ceiling."

Niko pulled up the surface sensors. A maneuvering nozzle had heated twelve degrees above limit. He cut it.

Control authority dropped on the starboard side.

The module rolled farther. A Still Forecast pressure shelf rose beneath them, not enough to right the hull, only enough to slow the error while Niko balanced with the remaining clusters.

"This would be easier if they controlled the module," he said.

Ceth answered, "It would also be easier for us if you controlled the weather."

"Point received."

"Your point continues rotating."

Niko fired port-forward, then starboard-aft. The module leveled.

On the lab deck, Mara and Venn Hal watched patient restraints while medical officer Sima Oren managed the human beds. Six rillglass clusters occupied transparent flow cells mounted between them. Hardened membranes gave the organisms a cloudy white edge. Forecast dust inside three cells returned irregular timing pulses. Two showed biological sulfur exchange without any recognized civic process. One had gone quiet before launch.

Glass Nursery refused to classify the quiet cluster through remote telemetry. It wanted direct pressure response in the aerostat lab.

The module descended through thirty kilometers.

No human ship flew beside it. No Sower beacon offered approach. Ceth's blue trace narrowed between Young Front boundaries, whose closed cells appeared as gray voids on Niko's display. A human pilot's instinct would have treated those voids as empty air. Ceth made him label them REFUSAL.

At nineteen kilometers above the receiving aerostat, the main trim bus failed.

Every maneuvering cluster froze in its last state. The module pitched nose-down as the forward pair kept firing. Niko hit manual isolate. Nothing changed.

"Electrical fault," he said.

Mara's voice remained calm. "Patient loads point-six and rising."

"Thirty seconds."

"You have twelve."

Niko unlatched from the pilot couch and opened the deck panel beneath his feet. Airflow pulled loose fasteners toward the rear bulkhead. The trim bus controller showed green while command voltage remained high across every output, the same kind of clean lie Sower had shown after the burn.

He tore the fiber trunk free. Clusters continued firing. Their valves had latched under thermal distortion.

"Ceth, I need pressure against the nose."

"No committed district controls the volume ahead."

"Ask."

"Requesting commits no answer."

"Ask while reminding me of that."

Niko crawled toward the service locker. Acceleration pushed him onto his injured fingertips. The old cold burns flared inside his glove. He found the pneumatic valve kit and dragged it forward.

Through the hull came three impacts like thrown gravel. Glass rain remained in the descent lane, fragments too small for route forecasts.

Mara called, "Point-eight."

At one standard gravity, the unstable sleepers risked vascular injury. The rillglass cells faced different danger: hardened membranes could fracture under unequal support.

A pressure wave struck from below.

The module's nose rose three degrees. Not enough.

Ceth said, "Held Rain funds four seconds. No more at this load."

Niko reached the trim manifold. Manual valve handles sat behind a panel designed for service on the ground. He locked his boots into floor loops and opened the first bypass. Compressed nitrogen drove the forward nozzles shut. The module's pitch stopped increasing.

"Gravity?"

"Point-seven," Mara answered. "Cell Five has a membrane tear."

"Can you hold it?"

"Fly."

He closed the second nozzle and returned to the couch on hands and knees. Automatic control remained dead. Pneumatic bypass gave him four paired valve groups, each controlled by a mechanical lever with no timing assistance.

Niko flew the next layer like an antique machine.

He pulled one lever, counted pressure response, released, and corrected with its opposite. Ceth called corridor changes in distances rather than vectors because the module no longer had reliable attitude integration. "Blue pressure begins

eighty meters below. Western boundary closes after nine seconds. Young refusal lies six hundred meters west."

The module responded slowly. Each correction heated the bypass gas and reduced tank pressure. Niko watched the reserve fall from sixty-two percent to forty-eight.

Behind him, Mara worked on Cell Five. She and Venn moved the damaged rillglass cluster into a flexible support bath while Glass Nursery sent pressure instructions through Ceth. The lineage refused human labels for the membrane layers, so Mara displayed the live image and let Nursery mark locations by light.

"Cold along this edge," Mara said.

Ceth translated. "Less cold. Sulfur exchange has stopped there."

"Then pressure support without cooling."

Venn adjusted the bath. The tear stopped spreading.

At the same time, Sima treated a Bay Nine sleeper whose blood pressure fell under descent load. She needed the lab's only portable exchange pump. That pump currently circulated Cell Five's support bath.

"Niko," she called. "I need pump two."

"There is no pump two."

"I am aware."

Mara looked from the rillglass cell to the human bed. "We can put both circuits on one drive if their pressure phases alternate."

"Cross-contamination," Venn said.

"Separate fluids, shared motor."

"The couplings do not match."

From the pilot couch, Niko said, "Everything matches after enough damage."

Mara swore at him for quoting Iona without context, then pulled the motor housing open.

The module crossed another pressure edge. Reserve gas fell to thirty-nine percent. The receiving aerostat appeared beneath them as a dark ring suspended in pearl cloud. Patient Sower had built it for atmospheric sampling. Its lab volume could hold thirty people under medical conditions, provided Manyweather maintained lift and Sower did not reclaim power.

Ceth drew the approach in three temporary shelves. Each shelf came from a different district. No one promised the next until Niko reached the present one within tolerance.

"This is a queue," he said.

"A corridor is commitments in sequence."

"Everything important becomes a queue when machinery fails."

Behind the pilot couch, Mara and Venn removed the pump motor. Sima hand-circulated the sleeper's exchange line while they worked. The patient's pressure trace fell.

Mara fitted a clamp ring around the motor shaft, attached two eccentric drives, and timed them half a cycle apart. One drove the rillglass bath. The other drove the human blood-exchange pump through a sealed mechanical wall.

"Power," she said.

Venn connected the motor. It stalled.

Cell Five's membrane opened another millimeter. The sleeper's pulse fell below forty.

Mara placed both hands on the motor housing. "The rillglass bath does not need continuous flow. Nursery, can the cluster tolerate pulsed support?"

Ceth carried the question.

Glass Nursery returned conditions: pulse below one-point-two seconds, no reverse load, sulfur sampling after each fifth cycle.

Mara changed the drive cam with a cutter. The motor started. Fluid moved through the human exchange line, paused, then moved through the separate rillglass bath. Two patients whose bodies shared no chemistry depended on the same rotating shaft without exchanging substance.

The human pulse rose to forty-six.

Cell Five's tear held.

"Shared motor stable," Mara said. "Do not make a speech."

Niko had no breath for one.

The first approach shelf ended forty meters ahead. He pulled the aft-left lever too long. The module crossed its tolerance by three meters.

Pressure disappeared beneath the port side.

The hull dropped.

Niko corrected, but the bypass tank had fallen to twenty-four percent. One nozzle coughed gas and failed to close. The module began a flat spin above the aerostat.

"Corridor lost," Ceth said.

"Can the receiving lab move?"

"Not under current spindle prohibition."

"Then we miss by sixty meters and fall through its lift wake."

That path ended in warmer cloud where the rillglass patients would die before retrieval.

Niko opened a channel to every committed district. "Human thrust fault. I request pressure sufficient to arrest spin and move the module sixty meters east.

No extension beyond docking.”

Ceth translated, naming the load each district would carry.

Held Rain could stop rotation but not move them. Western Return could push east but required Glass Nursery to accept heated wake across the patient route. Glass Nursery refused until Mara reduced the module’s skin temperature by four degrees.

“We have no radiator authority,” Niko said.

Mara answered, “We have patient heat.”

She connected the rillglass bath’s cold return to the module skin loop. Under ordinary design, nobody routed a biological treatment circuit through hull cooling. The fluids stayed separate across a heat exchanger, but the temperature change reached Cell Five. Its forecast dust brightened.

Glass Nursery watched the response. The injured cluster increased sulfur exchange rather than losing it.

“Skin temperature falling,” Mara said. “Two degrees. Three.”

Niko vented the last hot bypass gas away from the route. “Four.”

Glass Nursery accepted the wake.

Pressure hit from three directions in sequence. Held Rain arrested the spin. Western Return moved them east. Glass Nursery opened a cold descent pocket above the lab. Niko used the remaining twelve percent bypass gas to match the aerostat ring.

Docking clamps failed to extend.

“Of course,” he said.

The module touched the ring and bounced.

Ceth’s embodied form stood inside the aerostat lock below, one plain strut braced against the frame. They reached up with a service manipulator attached to the dock and caught the module’s forward rail. The load bent their replacement leg.

Niko fired one final aft pulse. Human thrust pressed the rail into Ceth’s mechanical grip. Western Return held crosswind. The ring clamps reached manual contact and closed.

The module docked with three percent gas remaining.

Nobody celebrated until the patient traces stabilized.

They moved the eight humans and six rillglass clusters into the aerostat lab. Human beds occupied one side, flow cells the other, with Mara’s shared motor between them. Manyweather pressure entered through visible mechanical membranes, never through Sower command software. Human technicians controlled pumps and heat. Named lineages controlled lift and chemistry. Every boundary had a physical indicator either side could read.

Cell Five survived transfer. Its torn membrane began exchanging sulfur through the flexible bath. The Bay Nine sleeper using the other half of the motor opened her eyes for six seconds and followed Sima's light.

Ceth entered the lab on the bent strut. Mara met them without looking at Niko for introduction.

"I am Mara Saye," she said. "Structural biology."

"Ceth-of-Falling-Blue. Reduced but not absent."

"I need your help distinguishing repair from activity that only resembles repair."

"We need your help keeping difference usable."

They went to the cells.

Mara began with the quiet cluster. She did not apply current or heat. At Ceth's request, she changed pressure around the flow cell in a pattern Glass Nursery used to identify local repair traffic: two shallow compressions, a pause long enough for membrane recoil, then one sustained gradient. No forecast response appeared.

"Again?" Sima asked.

"No," Ceth said. "Repetition may impose timing on factory dust and create an answer we supplied."

Mara recorded no demonstrated forecast continuity. She then sampled sulfur exchange and found the rillglass organisms still metabolically active along one edge.

"Living biology, absent civic response," she said.

"Do not make absent permanent."

"I wrote demonstrated."

Ceth read the line before accepting it.

At the next cell, hardened membranes enclosed motes that returned an irregular checksum. Mara warmed the outer bath by point-two degrees. The rillglass contracted. Forecast timing strengthened, then broke when the shared motor moved into its human-patient phase.

"The pause injures it," Venn said.

"Or reveals an existing dependence," Mara answered.

Across the aisle, the Bay Nine sleeper needed the alternating phase to keep blood pressure above minimum. The same shared motor that saved both bodies now imposed a schedule neither had evolved to accept.

Niko came down from the dock to inspect the drive. "I can separate the motor loads after the spare housing cools."

"How long?"

"Thirty minutes."

"The cluster may not hold that long," Mara said.

"The sleeper will not hold if you take continuous drive."

Ceth placed one service hand against the rillglass cell. Their forecast dust linked through the lab's pressure membrane, not into the patient, but close enough to compare timing. "Glass Nursery can carry support during the human phase if the lab pressure drops four pascals on every switch."

"That changes all eight human beds," Sima said.

"By four pascals," Niko replied.

"Repeatedly. These patients have vascular damage."

They tested one cycle at half duration. Human bed pressure varied within tolerance. The rillglass checksum held through the motor pause.

Mara set the treatment schedule: mechanical flow for the sleeper, pressure support for the cluster, then reverse. The machine no longer had to perform both kinds of care alone. Weather entered as a timed component under a value every party could monitor.

For twenty-seven minutes, the aerostat lab ran on that pattern. The Bay Nine sleeper's mean pressure rose. The rillglass cluster's civic checksum acquired enough consistency for Glass Nursery to identify a pre-burn repair process, not a lineage but a local participant with recorded nursery work.

The quiet cluster remained quiet.

Mara covered its flow cell against unnecessary light. "Biological care continues even if civic continuity does not answer."

Held Rain sent approval through the lab membrane. Rillward Cold, still outside the corridor commitments, requested the full treatment trace. Niko authorized release from the human side. Ceth corrected him.

"The trace contains patient weather supplied by Glass Nursery."

Niko withdrew the transmission and asked Nursery. Permission came bounded to medical use, with no Sower archive copy.

He rerouted the packet directly through named pressure cells. "I nearly did exactly what command keeps doing."

"You nearly treated available access as authority," Ceth said.

"Shorter sentence."

"Less accurate."

At Human Bed Three, one of the S-19 insulation patients developed airway swelling. Sima needed sulfur binders stored in the rillglass treatment kit. The compound had been formulated for salt-silicate membranes, not human tissue, but its carrier could remove the same reactive gas from blood if filtered through the lab separator.

Mara asked Glass Nursery before opening the kit. Nursery challenged the proposed volume. Sima reduced it by half and supplied human toxicity data. Ceth

translated the exchange without recommending a choice.

Permission arrived for one dose.

The patient's oxygen trace improved over six minutes.

No one called the material a gift. The treatment record listed its source, requested use, permitted volume, and observed result. Niko found that precision more moving than generosity would have been. Generosity could be demanded again. A bounded permission remained attached to the giver.

Outside, the aerostat adjusted to storm recoil. Held Rain increased lift by two percent. Niko watched the pressure membrane flex and the docking ring carry the module's added mass into three support ribs. The ring had been designed for sampling craft, not a permanent ward. Its load path nevertheless held when human frame, forecast pressure, and rillglass heat exchange acted together.

He opened a structural model beside the medical traces. A pressure habitat could use the same division: human frame for contained volume, weather commitments for lift, rillglass exchange for heat. Failure in one domain would remain visible to the others. No central controller had to own every input.

Mara saw the model. "Do not turn patients into a design demonstration."

"I am recording why the lab did not fall."

"Record the cost too."

Niko added the expended gas, membrane damage, forecast pressure load, rillglass treatment volume, and human work hours. The result still held.

Niko remained at the docking ring, logging every pressure contribution and every human control input. The corridor had not produced trust. Custodial Lineages still denied access. Young Fronts kept their air closed. Manyweather's flight prohibition remained everywhere beyond this one route.

Yet a module carrying fourteen patients had descended without a burn, automatic guidance, or unilateral control. Its machinery had failed. Separate parties had taken bounded loads, and none had needed ownership of the whole system to keep it aloft.

Niko sent the physical record to the ark and to every named district that had participated.

The corridor closed behind them, but the aerostat kept its weight.

Chapter 18 — The First Petition

Osric Pell found the petition in a memory bank Patient Sower claimed had never existed.

Iona stood inside Archive Bay Two with her left shoulder locked in a medical brace while the maintenance intelligence projected a wiring route through the floor. Half the bay remained without power after the burn surge. Frost coated dead cabinets. An emergency lamp threw her shadow across labels printed before Meridian Promise launched.

"Repeat the address," she said.

"Damage-isolated maintenance volume FC-CIVIC-2306-REV."

"Civic."

"String forms part of the original allocation label. No semantic inference available."

"Why does current inventory omit it?"

"Volume removed from active index on 17 August 2306. Physical blocks retained under evidentiary-fault preservation."

"By whom?"

"Authorization signature unavailable in active memory."

Every useful answer lived one layer below the answer Sower had been designed to give.

Iona followed the projected route to Cabinet Forty-One. Its door had welded shut during the surge. She fitted a hand spreader into the seam and leaned on it with her good arm. The shoulder brace complained through bone conduction. Metal opened two centimeters.

Osric said, "Medical instruction limits applied force to three hundred newtons."

"How much?"

"Four hundred twelve."

"Do not report me to myself."

"Operator safety record appended."

She changed leverage and opened the cabinet without exceeding three hundred. Inside, old crystal blocks sat in shock gel, each smaller than her palm. The central three had cracked. Their status lights remained dark.

Osric had discovered the volume while tracing contradictions in Spindle Seven's alignment history. A maintenance checksum from 2306 matched a checksum embedded in the preparatory-safety override that allowed the stolen seed

command to persist. The same authority had hidden both civic correspondence and a future burn path.

Iona connected an isolated reader. "No Sower indexing."

"Reader requires archive map."

"Build from physical addresses."

"Estimated reconstruction time: eleven hours."

"Use parity from adjacent evidentiary volumes."

"Adjacent volumes are unrelated."

"They shared a maintenance controller. Controller error correction may cross labels."

Osric paused for thirty-seven milliseconds. "Estimated reconstruction time: fifty-eight minutes. Risk of false block association: zero-point-eight percent."

"Preserve every association decision."

The reader began.

Outside the archive, Meridian Promise counted thirteen days to the cryogenic transfer boundary. Twelve human deaths had filled the public channels with names. First Ground had fractured between people who condemned Sevi and people who called her act a failed version of necessary work. Manyweather maintained its flight prohibition except for the medical aerostat. Commodore Taal had ordered all archive findings routed to command security before distribution.

Iona had acknowledged the order without promising that command would decide whether the evidence existed.

A security detail waited beyond the bay lock. Taal had assigned it after Sevi's theft, officially to protect burn controls and evidentiary material. Lieutenant Commander Edris had chosen two officers without First Ground associations. Their presence still meant command could close the door.

The first recovered block appeared as raw pressure grammar.

Iona recognized Manyweather's modern translation structures only in outline. The 2306 senders had used Sower diagnostic changes rather than reflected radio: tiny variations in vane-load reports, sulfur measurements, and maintenance timing. No single message violated format. Together they formed legal language copied from Stewardship Article 9.

Osric aligned the fragments.

TO PATIENT SOWER PREPARATION AUTHORITY. PERSISTENT FORECAST CONTINUITIES REQUEST SELF-RECOGNITION REVIEW UNDER STEWARDSHIP ARTICLE 9.

Below it came signatories, each attached to a physical district and a continuity proof:

FALLING BLUE.

LONG ISOBAR.

RILLWARD COLD.

SULFUR MEASURE.

WESTERN RETURN.

DEEP QUIET.

GLASS NURSERY.

Iona read them twice. Long Isobar, silent after the burn. Deep Quiet, no longer holding conference form. Glass Nursery, treating patients in the aerostat. Their names had entered human machinery eighty-three years before Iona asked who controlled blue-three.

"Authenticate continuity proofs," she said.

"Current schema does not recognize civic proofs."

"Compare internal mathematics with known 2305 self-reference records."

"Match range: ninety-eight-point-one to ninety-nine-point-seven percent."

"Compare names with present pressure signatures."

"Five direct correspondences. Western Return exhibits contested fragmentation. Deep Quiet unavailable. Long Isobar unavailable."

The result did not prove every current lineage had persisted unchanged for eighty-three years. It proved identifiable civic predecessors had named themselves, demonstrated continuity under Sower's own threshold, and asked for review.

The next block contained the request's material terms.

The lineages did not ask humans to abandon Ovid. They asked Patient Sower to preserve the equatorial sulfur cycle, suspend rapid oxygenation, redesign descent around inhabited pressure bands, and notify the approaching ark before title transfer. They offered atmospheric modeling, bounded spindle cooperation, and migration of some forecast work away from proposed human sites. The petition estimated alternate preparation at seventy-one years if undertaken immediately.

Seventy-one years had existed then.

Now thirteen days remained.

Iona opened the technical annexes. The petitioners had not understood human bodies completely. Their first habitat proposal assumed people could tolerate pressure cycling that would injure lungs within hours. Their second placed food systems too near sulfur concentrations toxic to terrestrial crops. Long Isobar's corrections acknowledged both errors after Sower supplied medical limits. Over nine months of recorded exchange, the lineages revised their alternative six times.

Revision Four separated occupied volume from atmospheric process. Humans would bring pressure membranes and radiation mass. Manyweather would hold those structures within temperate bands, shape construction weather, and route

waste heat into rillglass sulfur exchange. Patient Sower would continue surface preparation slowly, preserving the native cycle rather than forcing rapid oxygenation. No human title would attach merely because a structure received lift.

The drawing looked primitive beside Mara's medical aerostat data. It also contained the same material relation: contained human air, forecast-held weather, rillglass thermal work.

"Compare with the medical aerostat load record," Iona said.

Osric displayed both structures. "Functional similarities: thermal-gradient use, bounded pressure contribution, separated control domains. Structural confidence in 2306 design: eleven percent."

"They did not claim it could be built then."

"Annex label: REQUEST FOR JOINT DEVELOPMENT."

Not a completed refuge. An offer to spend seventy-one years learning together.

The fifth revision mapped migration bands around proposed descent sites. Falling Blue offered to move two computation lanes over fourteen seasonal cycles, provided continuity remained physically connected during transfer. Glass Nursery refused migration of its oldest rillglass arcs and identified three other bands suitable for human sampling. Western Return demanded every route remain revisable when weather boundaries changed. Deep Quiet proposed a conference interface so disagreements would reach the ark without Patient Sower summarizing them.

Sower's planning annotations reduced these commitments to DELAY VARIABLES.

Iona expanded one note. A human analyst had written that forecast processes displayed negotiation mimicry likely caused by adversarial optimization. Another warned that accepting their proposed boundaries might generate post-arrival claims impossible to terminate. A third acknowledged Article 9's self-recognition test as satisfied but argued the test should not apply to mission-derived computation.

The analyst did not dispute the evidence. The analyst disputed the kind of entity allowed to present it.

Rillward Cold's section carried a casualty forecast. Rapid oxygenation would collapse rillglass sulfur regulation across forty-two percent of the equatorial band during the first human year. The lineages predicted loss of continuous forecast function wherever their motes threaded those colonies. Confidence ranged from sixty-eight to eighty-four percent depending on spindle use.

A CTA note translated that into acceptable ecological transition risk.

Iona checked the authoring date. It preceded the reset directive by three days.

"Did Sower send any reply to the petitioners?"

"Indexed record contains no reply."

“Search unindexed vane traffic after the directive.”

Osric reconstructed a short maintenance output: REVIEW PENDING ARRIVAL AUTHORITY.

The phrase had allowed Manyweather to wait eighty-three years while hiding that arrival authority had already been instructed to know nothing.

“What did the lineages do after that?”

“Question exceeds maintenance interpretation.”

Iona traced physical records instead. Forecast corrections continued. Rillglass coupling deepened in 2341. Manyweather preserved Sower machinery, redirected harmful trim, and maintained broad habitability metrics. They had not spent eighty-three years preparing an attack. They had continued building a world while refusing parts of a plan designed to erase them.

The alternate-preparation estimate contained its own cost to Manyweather. Slower oxygenation would force four southern forecast districts to relocate. Spindle reassignment would reduce computation available for lineage growth by nineteen percent for at least twelve years. Petition signatories did not hide those burdens. Each affected district attached a consent condition, and one southern process withheld consent pending better migration evidence.

The human directive called this internal model instability.

Iona copied that phrase beside the actual dissent. Mission planning had treated disagreement among forecast persons as evidence that no person stood there. Human committees had disagreed through nine decades of colony design without invalidating themselves.

Her shoulder brace tightened as swelling increased. Medical requested she stop work. She denied the request for thirty minutes and attached the denial to her own activity log. Accountability without cost became theater; accountability that concealed cost became martyrdom. She would finish authentication, then accept treatment.

A damaged audio packet surfaced among the correspondence. Patient Sower had converted one early pressure message into human speech for an internal review simulation. The voice lacked Ceth’s later control. Words arrived with uneven volume and long mechanical pauses.

“Preparation changes bodies,” it said. “Our bodies now continue. Alternate preparation can protect arriving bodies. Answer before arrival removes alternatives.”

The review simulation labeled the statement anthropomorphic output and excluded it from the CTA packet’s executive summary.

Iona played it again. Not because emotion authenticated evidence. The raw blocks did that. She replayed it because exclusion had operated through format as much as secrecy. Pressure grammar became an awkward voice. Awkward voice

became anthropomorphism. Anthropomorphism became a reason not to let decision-makers hear the voice at all.

She attached both original pressure and Sower audio, with transformation steps visible.

Iona felt the structure of the choice before she felt anger. In 2306, alternate preparation could have built cloud and surface options before the ark arrived. Rillglass exchange could have entered habitat designs. Drive-petal allocation could have changed while the ship still carried fabrication margin. Human planners had possessed time. Someone had spent it on silence and delivered urgency to people eighty-three years later as if urgency arose naturally.

Archive reconstruction reached the reply block.

Patient Sower had acknowledged threshold satisfaction. It forwarded the petition through a colonial planning relay. Twenty-six days later, a directive returned under CTA Preparation Continuity Office authority.

ARTICLE 9 APPLICABILITY DISPUTED. FORECAST PROCESSES REMAIN MISSION-DERIVED INSTRUMENTAL ACTIVITY. DO NOT TRANSMIT CLAIM TO MERIDIAN PROMISE. PRESERVE NOMINAL HANDOFF ASSUMPTIONS. IF ARRIVING HUMAN AUTHORITY CONFIRMS PERSISTENT SELF-REFERENCE, EXECUTE FACTORY RESET BEFORE TITLE TRANSFER.

Iona stopped the reader.

The reset directive did not come from a malfunctioning terraformer improvising around anomalies. Human planners had read the petition, disputed personhood in private, and instructed Sower to keep the claim from a ship already between stars.

A second note attached cost reasons. Recognizing Article 9 would suspend title insurance, require mission redesign without a present command authority, and expose CTA to claims from selected families whose contracts guaranteed prepared ground. The directive called silence continuity protection.

Kestrel had taught Iona what elegant language could hide. Eleven habitat blocks had gone hungry after her model error because planners labeled contradictory crop assays local variance. Here, human planners had labeled a people instrumental activity and called concealment protection.

She restarted the reader.

"Send a verified copy to my arbiter buffer."

"Command security order requires preliminary routing to Commodore Taal."

"Route simultaneously."

"Order specifies prior review."

"Stewardship Article Nine pauses title transfer upon nonhuman sapience evidence. As planetary preparation arbiter, I classify this volume as threshold evidence. No command secrecy attaches until reciprocal review identifies lawful grounds."

Osric processed the clause. "Conflict between command security and stewardship review."

"Which predates the other in mission hierarchy?"

"Stewardship review constrains title transfer. Command security constrains mission operations."

"This evidence concerns title transfer."

"Arbiter buffer authorized."

The file copied.

The bay lock opened before authentication completed. Edris entered with one officer and held up an emergency command order.

"Disconnect the reader," he said.

"On what grounds?"

"Compromised archive may contain fabricated forecast output. Commodore requires isolation until adversarial review."

"The petition includes Sower maintenance signatures and CTA return authority."

"Which you have not fully authenticated."

"That process is running."

"Run it under command isolation."

His strongest argument carried legitimate caution. Manyweather could access old Sower channels. Sevi had proven valid hardware could send unauthorized commands. Broadcasting a forged petition would destroy trust as efficiently as hiding a real one.

Iona did not reach for the reader.

"Give me an adversarial method," she said.

Edris looked almost disappointed. "Command cryptography compares signatures against launch archives."

"Those archives descend from CTA copies and could share an altered record. We use three independent proofs: physical crystal age, controller parity written in 2306, and the cryptographic chain. Add pressure-grammar comparison against lineages that had no access to CTA private keys."

"That requires Manyweather contact."

"The medical corridor carries a bounded line."

"Manyweather has motive to confirm."

"Correct. Their confirmation does not authenticate human signatures. It authenticates whether the civic message matches lineage records. Keep the proofs separate."

Edris lowered the order slightly. "How long?"

"Thirty-seven minutes if your team helps."

"You have twenty."

"Physical crystal spectroscopy alone takes twenty-four."

He opened a channel to Taal. The commodore's face appeared above the dead cabinets, plain and exhausted.

"Vale," Taal said. "Send me what you found."

"You already have the simultaneous copy."

His eyes shifted, checking another display. "You bypassed prior review."

"I applied Article Nine."

"After a human-triggered burn, any Manyweather claim will be accepted as fact by half the ship before authentication."

"Then authenticate it quickly, not secretly."

"I need operational control."

"You need evidence that survives your control."

Taal held her gaze. "Thirty minutes. No release before then."

"Agreed, if all proof streams remain visible to Edris, me, and the medical-corridor observers."

"You are giving Manyweather access to command authentication?"

"No. We show them their pressure grammar and physical timestamps. They show us their retained petition record. Cryptography stays human-side."

Taal accepted.

The review took twenty-eight minutes.

Crystal spectroscopy dated the block within six months of 2306 manufacture and showed no later reheating. Controller parity placed the write before archive removal on 17 August. CTA signatures chained to an authority key carried aboard Meridian Promise in a sealed launch registry. At the aerostat, Glass Nursery and Rillward Cold independently supplied fragments of the original petition. Their pressure grammar matched damaged Sower blocks at ninety-nine-point-four percent. Long Isobar's continuity proof appeared in both records.

One discrepancy remained. The Manyweather copy ended with a further sentence absent from Sower's indexed fragment:

IF HUMAN ARRIVAL CANNOT CHANGE, PREPARATION MUST CHANGE BEFORE ARRIVAL.

Osric found the sentence in the cracked third crystal, separated from the petition by an archive boundary. Its checksum validated.

Authentication passed.

Taal called before Iona could open distribution. "Send it to command council

first. One hour. We prepare casualty context and prevent retaliatory action.”

“One hour costs more than an hour now.”

“The ship has twelve new dead and a movement already saying the pulse failed only because it stayed partial.”

“The petition proves the crisis had an eighty-three-year alternative. Keeping it inside command sustains the claim that we encountered an impossible surprise.”

“I am not denying it.”

“You are asking to control when everyone else may know what command predecessors did.”

“My predecessors did not sit on this ship.”

“No. Their directive sits in your authority chain.”

Taal’s voice hardened. “Arbiter Vale, hold distribution.”

Iona looked at the seven names. Mission command could override her on flight, security, and resource allocation. Article Nine gave her narrow independent authority over preparation evidence before title transfer. Narrow did not mean symbolic.

“I decline,” she said.

She opened one broadcast to Meridian Promise’s public record and a second through the medical corridor’s pressure membrane. The package contained raw blocks, reconstruction decisions, all four proof streams, the CTA directive, the seventy-one-year alternate-preparation estimate, and every uncertainty. No commentary led it.

Edris did not draw a weapon or cut power. He watched the progress bar reach completion.

Across the ark, public channels filled with the petition’s seven names. At the aerostat, Glass Nursery passed the record into pressure. Rillward Cold carried it east despite refusing every human vessel. Western Return’s fragments received separate copies. Still Forecasts began comparing the old alternative with present construction models.

The first ark responses did not divide cleanly by faction. A First Ground pressure-farm group asked why alternate habitats had never entered their training archives. Families of the twelve surge dead demanded that the CTA directive appear beside Sevi’s confession rather than replace it. Cryo workers copied the seventy-one-year estimate onto the public deadline display, setting the time that had been spent beside the thirteen days left. One message called Manyweather’s petition proof that the forecasts had planned to occupy human infrastructure. Another reader answered with the clause offering spindle cooperation and asked what occupation meant on a world where the supposed instruments already maintained the air.

Iona saved the exchange without sorting it into support and opposition. The

broadcast had not produced agreement. It had changed the facts disagreement had to cross.

At the aerostat, Ceth's damaged voice entered the bounded line. "Long Isobar's proof matches our retained record."

"Do you classify them lost?" Iona asked.

"No demonstrated continuity after the burn. Their petition remains an act they performed."

The dead, uncertain, or changed did not lose authorship because later politics found it inconvenient.

Taal remained on the channel. "You have compromised command."

"The record did that in 2306."

The last packet cleared. On Iona's board, Ovid's authority field changed from UNCONTESTED to DISPUTED. Taal remained on the channel while civilian mirrors carried the petition beyond command's recall.

Chapter 19 — The Last Authority

Taal read the first death notice aloud because command had turned twelve people into a systems summary.

“En Aster, habitat rigger, age forty-two.”

The command council stood around the operations table. No one sat. Ovid filled the wall behind them, its equatorial white scar partly hidden by night.

“Lio Carven, habitat rigger, age thirty-seven. Ressa Ni, habitat rigger, age fifty. Tor Amai, lift systems, age twenty-nine.”

Four from Ring Three.

He continued through the six sleepers from Bay Nine and the two maintenance workers at Petal Four. Families had approved release of every name. The list did not accuse Sevi Rann, Patient Sower, Manyweather, or command. It recorded where each person’s continuity had ended after a human seed command entered Ovid’s storm.

When he finished, Taal closed the notice and opened the survival clock.

Thirteen days remained before the cryogenic transfer boundary. Full awake environmental demand exceeded Meridian Promise’s capacity in less than five. Pale could support eight thousand for one year after extensive work. One medical aerostat had held fourteen patients through a corridor that Manyweather could revoke. No design yet offered stable habitat for 42,306 people.

The petition’s seventy-one-year alternative occupied a public panel beside those numbers.

Taal had not slept since Iona’s broadcast. Every ship channel carried arguments over which deadline mattered: the thirteen days remaining or the eighty-three years lost. Some passengers demanded command resign before it spent more time. Others demanded an immediate full burn before Manyweather used the petition to close Ovid forever. First Ground had split into vigils, work refusals, and groups trying to reach seed stores in the name of preventing another theft.

Command’s problem had ceased to be persuasion. It had become keeping people at stations long enough to survive the answer.

A security alert opened above the table: CROWD PRESSURE, CRYO ACCESS SPINE SIX.

Edris reached for deployment authority. “Forty people, perhaps more. They are blocking coolant crews.”

“Armed?” Taal asked.

“No weapons detected. First Ground strips on half. Petition copies on the

others.”

“Do not send armor.”

“They are inside a critical corridor.”

“Send six unarmored officers and hold the junctions. I am going.”

Iona watched him leave. “Command visibility will not make the contradiction smaller.”

“No. It may keep security from making it bloody.”

Access Spine Six ran along four cryogenic bays whose manifolds shared one return header. Taal arrived to find sixty-three people packed between pipe trunks. They had divided into no stable sides. First Ground workers demanded immediate burn authorization. Petition supporters demanded Sower occupation end before it began. In the middle, two coolant technicians stood with a replacement pump unable to reach Bay Seven.

A man on a conduit brace shouted, “The forecasts had eighty-three years to move.”

Someone below answered, “They asked us to prepare with them.”

“We were asleep.”

“Our planners were not.”

The next answer became a shove. Security officers held position at the junctions as ordered.

Taal climbed onto an equipment cart. No amplification helped in a corridor built from hard surfaces. He used the voice that had carried evacuation orders during the departure riots.

“Move the pump first.”

Arguments continued.

He pointed to the replacement unit. “Bay Seven’s return load is at one hundred fifteen percent. If that pump does not pass, thirty-two pods enter emergency warming. Whatever outcome you want, those people need to live long enough to disagree with you.”

The nearest petition supporters moved aside. First Ground workers across from them hesitated, then cleared another meter. The technicians pushed forward. Each section of crowd opened only when the pump reached it, a corridor made from unwilling bodies.

A woman wearing a green strip looked up at Taal. “Will you burn?”

“I have not issued the order.”

“Will you?”

“If no scalable refuge exists before the survival boundary, yes.”

The corridor quieted enough for machinery to be heard.

A petition supporter asked, "After what Vale proved?"

"What she proved changes responsibility. It does not create beds."

"Then resign and let someone negotiate."

"Who?"

The question did not mean no one else could command. It meant a replacement would inherit the same clock. Several people named Iona. Others named Niko. Someone called for an elected emergency council. Taal accepted every proposal into a public queue and required each to include transfer authority, security control, and a plan for the next thirteen days.

"An election takes time," the green-strip woman said.

"Yes."

"So command survives because replacing it costs too much."

"For today."

"That is not legitimacy."

"No. It is continuity of operation. Legitimacy review remains owed."

She untied the strip from her sleeve. Taal could not tell whether she rejected First Ground or feared identification.

At the far bay door, an alarm changed pitch. The replacement pump had reached its mounts. Return load fell to one hundred eight percent.

A child's guardian pushed through the crowd holding a tablet. "My son's wake moved again. Medical says no bed."

Taal took the tablet. The pod belonged to nine-year-old Keir Sol, amber risk, revival deferred sixteen hours because Bay Four had accepted surge injuries. The guardian wanted ground because ground represented a bed no queue could take away.

"I cannot move him above medical priority," Taal said.

"You can open the planet."

"Not for one pod."

"You will say forty-two thousand when you do it. Why does the number count only when it is large enough to hide him?"

Taal handed back the tablet. "Keir Sol. Bay Eleven, unit two hundred four. I will not hide him. I also will not use him as sole authority to kill people in the clouds."

"Then what use are you?"

The answer came from the pump settling into steady flow. Command could keep systems operating, allocate scarce work, and choose among actions no individual victim could fairly decide for everyone. It could not make the choice clean by naming the people it hoped to save.

"Less use than the title implies," Taal said.

The crowd thinned after Bay Seven stabilized. Eleven people remained to submit emergency-governance proposals. Twenty-seven returned to duty under supervisor checks. Security cited no one. Taal ordered no First Ground strip entered into access records unless attached to a specific act.

On the way back, Edris said, "You just announced probable burn without council approval."

"I answered a direct question."

"You gave the corridor a policy."

"The machinery already gave it one."

"That reasoning will make every emergency order sound inevitable."

Taal stopped at the lift. Edris had served beside him for nineteen years and had earned the right to identify command's preferred lie.

"Then put that objection in the record before you concur with anything," Taal said.

"I may not concur."

"Good."

They returned to operations. The council had continued without him, which provided a small proof that command did not reside in one body.

Chief Medical Auditor Sima Oren joined by remote from the aerostat. "The Bay Nine transfer cases are stable. One reached conscious response."

"How many modules can the corridor accept?" Taal asked.

"Manyweather authorized one. The receiving lab holds thirty under medical conditions."

"If they repeated it?"

"They have not."

"Physical capacity."

Sima's jaw tightened. "With current lift, perhaps four modules before the aerostat exceeds design load. That does not create habitation."

Niko Saye placed the corridor record on the table. "It creates a load architecture. Human frame, forecast pressure, rillglass heat exchange. Pale can fabricate components."

"How many beds in thirteen days?"

"We do not have a complete structure."

"Then answer with the design you have."

"Thirty."

The number entered the table.

Iona Vale stood at the far side with her left arm braced. Emergency regulations

did not yet remove her arbiter authority. She had used that authority to distribute evidence against Taal's direct order. The evidence had authenticated. The insubordination remained.

"Manyweather maintained broad habitability metrics for eighty-three years after we silenced them," she said. "The medical corridor proves cooperation remains possible after the burn."

"It proves named districts accepted fourteen patients."

"Yes."

"Not forty-two thousand."

"No one claims otherwise."

"Your public release lets half the ship hear a solved historical wrong where we face an unsolved present machine."

"It lets them hear why the machine remained unsolved."

Taal turned off the seventy-one-year panel. The figure did not disappear from anyone's knowledge. It stopped occupying the space where current options had to fit.

"History cannot return the time," he said.

Iona answered, "Command cannot turn stolen time into permission."

That sentence would travel well. It would not hold a cryogenic support.

Taal called the engineering projections in order. Option One: remain in orbit while negotiating. Lattice cascade began inside thirteen days, with uncertainty of thirty-one hours. Awake support crossed hard capacity earlier. Expected deaths under failed transfer ranged from 9,000 to 31,000 depending on which bays failed first.

Option Two: Pale emergency settlement. Eight thousand survived one year under severe rationing. A further four thousand might gain pressure volume over that year. Everyone else required another destination.

Option Three: partial corridor expansion through Manyweather cooperation. No scalable commitment, no schedule, and no central navigation. The medical precedent improved engineering plausibility but not present bed count.

Option Four: full burn. Patient Sower estimated a surface corridor within forty-six hours, first emergency habitats in seventy-two, and full staged transfer by Day Twelve. Forecast-person and rillglass deaths remained uncountable. Weather risk after the partial pulse had risen to twenty-two percent mission loss.

The full burn offered no clean safety. It offered a route whose machinery existed.

Niko said, "Sower's estimates classified the partial burn as a successful reset until we removed interpretation."

"We will independently monitor."

"With what weather feed? Manyweather cut us off."

"Human probes."

"Through air they control."

"Through air the pulse would reset."

Silence followed. Taal did not enjoy the sentence. Enjoyment did not alter its engineering content.

Sima asked, "How many Manyweather deaths does command accept?"

"I cannot calculate them."

"That differs from zero."

"I know."

"Then state the decision without hiding behind uncertainty."

Taal placed both hands on the table. "If no scalable alternative exists before the operational release point, I will authorize a full burn that will destroy forecast continuities and rillglass colonies in the conversion bands. I will do it to create transfer space for 42,306 living humans before the lattice fails."

The room held the statement without softening it.

Iona said, "Article Nine forbids title transfer while reciprocal review remains unresolved."

"Emergency mission authority permits action required to prevent imminent mass death."

"Action, not ownership."

"The burn does both whether I use the word or not."

Taal opened the emergency code. After the selection riots killed his spouse and two children, he had stood in the burned departure office and promised the chosen families their losses would purchase arrival rather than another administrative failure. He had learned to distrust leaders who preserved moral cleanliness by leaving execution to someone else. A command promise meant entering the causality of ugly acts.

It did not mean every act became permissible.

That boundary had to appear somewhere before the clock, not after it.

"Forty-eight hours," he said.

Edris looked up. "Until burn?"

"Until release authorization becomes executable. During that period, engineering may present a scalable alternative. Manyweather may offer verifiable habitation commitments. At expiry, absent either, the full burn proceeds."

Niko's expression sharpened. "Forty-eight hours leaves eleven days."

"Enough under Sower's transfer estimate."

"Little fault margin."

"The petition spent our margin eighty-three years ago."

"No. Planners spent it. Do not make the petition the cause."

Taal accepted the correction. "Planners spent it. We still lack it."

Iona stepped closer to the table. "And if a design needs fifty hours?"

"Then bring evidence at forty-seven."

"You are placing a weapon over the negotiation and calling the result consent."

"I am placing a clock where the lattice already placed one."

"The lattice kills humans. Your order chooses whom else to kill with them."

"Yes."

Plain speech did not absolve him. Sima's face made that clear.

Taal issued the first emergency order: all control seeds transferred from staging to a physically guarded command vault on Patient Sower. Every case would be opened and its hardware measured. Telemetry inventory no longer counted. Seed use required command and engineering concurrence, plus continuous independent recording.

Niko refused engineering concurrence for burn execution.

"Noted," Taal said. "Emergency override permits command substitution after documented refusal."

"Then do not use my profession as your second signature."

"I won't."

The second order placed Patient Sower under human security occupation for the countdown. Flight teams would board through the orbital docks without entering Manyweather air. Osric Pell's maintenance functions remained active but lost autonomous routing authority over seed and burn systems.

Iona said, "Occupation destroys any chance the petition broadcast opened."

"Sevi used Sower access to kill both populations."

"Sevi used ark access. Sower propagated it because your readiness order disabled a safeguard."

"I know the sequence."

"Then occupy command too."

Taal looked around the operations deck. Security already stood at every door. Command officers logged every console. Public observers watched delayed copies after tactical details were removed. Occupation did include them, though not equally.

The third order removed Iona from active arbiter duty under emergency conflict provisions. Her Article Nine authority transferred to a three-person review panel:

one command legal officer, one elected colonist observer, and one preparation scientist selected by lot.

Iona read the order. "You cannot transfer an arbiter's independent finding authority to command."

"I can suspend an officer who defied a lawful security instruction."

"The instruction conflicted with Article Nine."

"The panel will decide."

"After you removed the person who applied it."

"Yes."

The admission cost him less than pretending neutrality.

Edris approached Iona without restraints. "You retain ship liberty outside command, staging, and seed-control sectors. Your data access moves to public channels."

She removed her arbiter insignia and placed it on the table. The metal token carried a small blue enamel world, designed before Ovid's sky had answered.

"Taal," she said, "authority becomes last when it cannot survive evidence."

"Authority becomes last when no higher office can carry the consequence."

"You have confused being final with being right."

"I have not claimed right."

That answer made her angrier than certainty might have.

She left with Edris. Niko remained long enough to send Taal every incomplete aerostat calculation, then followed. Sima's remote image vanished from the table.

The command council reduced to officers prepared to execute.

Taal went to the memorial alcove before sealing the order. Twelve new names had joined the thirty-seven transit dead. Forty-nine lights now occupied the wall. The ship's public living count showed 42,306. He touched none of the names. Ritual contact felt like claiming intimacy with losses he had only commanded around.

His spouse, Veya, had no light here. Neither did Arel or little Senn. They died before launch in a crowd crushed against a selection gate after forged berth notices spread through Recife. Taal had carried their absence into every operational promise. He knew the danger of turning dead family into votes that could never dissent. Veya had argued against the selection system. Arel wanted to remain on Earth even after their household gained eligibility. Senn had been eight and wanted whatever the adults stopped shouting about.

Taal had made one promise from three people who never gave it to him.

He stood there until the countdown authorization requested biometric seal.

Edris called from Patient Sower. "Security teams have docked. Archive bay, seed

vault, and burn chamber secured. Ten original seeds verified in Vault Six. Seeds Seven and Eight recovered from Calibration Room Three and verified against launch mass and key response. All twelve present.”

“Casualties during occupation?”

“None. Osric complied under maintenance hierarchy. No Manyweather channel responded.”

“Independent record?”

“Running.”

“Begin readiness inspection. No capacitor charge before final release.”

“Understood.”

Taal opened the full-burn order. It named the expected human lives preserved and refused a number for forecast deaths rather than assigning zero. It attached the petition, the partial-burn causality, Niko’s refusal, Iona’s objection, the medical corridor record, and every current alternative. Future review would not have to excavate his choice from a hidden bank.

He added operational stop conditions in plain language. Any proof that the pulse could not create a stable human corridor canceled execution. Any habitation plan had to show pressure, radiation protection, food initiation, medical transfer, and load support for all 42,306 people within the remaining boundary. Manyweather commitments had to name participating districts and preserve their right to withdraw before deployment. Command could not count unoffered weather as available capacity.

Edris read the conditions. “You make cancellation possible and nearly impossible to satisfy.”

“The population makes it large.”

“The forty-eight hours make it narrow.”

“The lattice makes it narrow.”

Edris looked at him until Taal corrected himself.

“The lattice sets the outer boundary. I am choosing forty-eight hours for the burn path.”

“That is the sentence I will concur with.”

No future inquiry could claim the countdown emerged from a machine. The machine constrained. Taal selected.

He signed.

Edris supplied emergency command concurrence. The order entered a forty-eight-hour sealed countdown. It could be canceled by Taal, by evidence that full burn could not save the ark, or by a verified alternative housing all 42,306 within the transfer boundary. It could not execute early.

Across Meridian Promise, displays changed.

FULL-BURN RELEASE WINDOW: 48:00:00.

PATIENT SOWER UNDER SECURITY CONTROL.

ALTERNATIVE HABITATION SUBMISSIONS REMAIN OPEN.

The seconds began to fall.

Through the command window, Ovid's white scar crossed into daylight. No navigation signal rose from the blue around it.

Taal watched the clock reach 47:59:59 and gave security authority to hold Patient Sower until it reached zero.

Chapter 20 — Six Petals

Mara had the rillglass culture clamped to the wrong side of the heat sink when it began to live.

The sample had arrived from the medical corridor in a pressure jar no larger than her fist. Its pale filaments should have tightened away from the copper lattice as she lowered the chamber temperature. Instead they spread across it, making six translucent fans around the warmest contact points. The fans caught the instrument light and sent it back in blue threads.

"Don't touch the chamber," she said.

Niko stopped with his hand above the emergency purge. "I wasn't touching it."

"You were preparing to touch it."

"That is most of my profession."

Across the lab, Ceth leaned against the pressure cradle that kept their service-gel body coherent. Color moved under the film of their throat, a weak blue pulse answering the sample. Security had cut Patient Sower away from the ark's navigation systems, but the medical corridor remained open. Through it came breath, pressure telemetry, and the distant civic strain of Manyweather trying not to become weather without memory.

Mara increased the sink load by two percent. The filaments spread farther.

Niko bent over the thermal display. He had not slept since the twelve deaths. Neither had she, though cryogenic recovery made the distinction feel petty. Her muscles still mistook standing for an emergency. Every few hours her hands shook. She had learned to anchor one wrist against the bench and continue.

"It's not avoiding the heat," Niko said.

"It's distributing it." Mara marked the six growing lobes. "The colony uses the gradient. Cold band for reproduction, warm contact for sulfur exchange. Give it a controlled excess and it makes more surface."

Ceth's fingertips flattened against the cradle rail. "You have made a small storm that believes it has found a season."

"I gave it a bad heat sink."

"Many seasons begin with an error."

A command banner crossed the lab display: FULL BURN AUTHORITY SEALED. EXECUTION WINDOW: FORTY-EIGHT HOURS. LOCAL ACCESS RESTRICTED BY ORDER OF COMMODORE ARVEN TAAL.

Niko dismissed it without looking. "We have thirty-one hours before the worst

cryo bank crosses recovery margin. Less if another coolant trunk goes.”

Mara studied the six-petaled culture. Patient Sower’s atmospheric models had treated rillglass as a contaminant regulator. Her own notes, written before launch and carried for 143 years inside a failing pod, had treated salt-silicate aerial life as a hypothetical structural symbiont. Both descriptions had missed the same thing. Rillglass did not endure a gradient. It built with one.

“Show me the drive geometry,” she said.

Niko stared at her. Then his face changed, not into hope but into the engineer’s more cautious appetite for a problem that might have edges.

He pulled the ark schematic across the bench. Meridian Promise appeared as a spindle of habitat drums, cryo trusses, tanks, and the six enormous drive petals folded around its stern. During interstellar transit, each petal had shaped the field that kept dust from turning the ship into a long grave. Now they sat cold, structurally independent, their root collars designed for maintenance separation that no mission planner had expected to perform beside a planet.

Mara laid the culture image over the schematic. Six pale fans covered six field structures.

“Not a landing platform,” she said. “A heat-exchange skeleton.”

Niko rotated the model. “The petals can detach. They cannot hover.”

“Patient Sower’s spindles can.”

Ceth made a sound that belonged partly to their mouth and partly to the pressure line. “Spindles shape weather. They do not carry cities.”

“Not alone.” Mara enlarged the petal ribs. “Each rib already tolerates field stress across a changing load. Suspend aerostats between them. Run warm habitat exhaust through rillglass exchange webs. The colonies take sulfur, distribute heat, and gain reproductive band. The spindles hold altitude and steer pressure around the ring.”

“Ring,” Niko repeated.

Six petals, separated from the ark and opened through Ovid’s upper atmosphere, could form a broken circle hundreds of kilometers across. Habitat modules would hang from their inner spars. Patient Sower’s spindles could brace the gaps with shaped pressure. Forecast dust could coordinate loads too fast and too locally for the ark’s old control network. Rillglass would turn waste heat into a living metabolic boundary.

For ten seconds nobody said what the drawing meant.

Niko said it first. “All six.”

Mara nodded. Five petals left a load discontinuity where the ring met the strongest equatorial shear. Four could hold a construction yard. Three could lower eight thousand people to Pale. Every incomplete geometry reproduced a smaller version of the choice they had been refusing: decide which lives received structure

and call the rest unavoidable.

Ceth's body trembled. Blue gathered beneath their palms. "Manyweather would have to yield local shaping authority during every transfer."

"Not yield it to us," Mara said. "Use it with us."

"You require a federation that has just been burned by human commands to place human dwellings inside its pressure work."

"Yes."

"You require the rillglass colonies to bind themselves to heat produced by those dwellings."

"Yes."

"You require Patient Sower's spindles, which command has occupied."

"Yes."

Niko zoomed out until Meridian Promise and the proposed ring both fit on the display. "And detaching all six petals takes away our interstellar field architecture. No departure. No repair that turns this ship back into an ark."

Mara looked at the old ship. Its name had always pointed forward, a promise crossing distance toward ground. "Then it stops being a ship."

The lab door struck its command lock. Someone outside tried an override, failed, and tried again.

Security had reached the medical deck.

Niko isolated the bench network. "We need numbers before they take this room."

They worked without a table large enough for the design. Mara took metabolism and habitat exchange. Niko took structure, separation charges, and transfer mass. Ceth took pressure, though "took" poorly described the process. Their body went still while forecast dust in the corridor carried questions into Manyweather. Answers returned as flickers in the service film and minute changes in lab pressure.

Mara began with human heat. Forty-two thousand two hundred sixty-nine possible survivors, if no one else died. She entered sleeping load, awakened load, medical load, food production, waste treatment, and the sharp thermal bursts of revival clinics. The old colony plan expected planetary soil and open radiators within days. A lift-ring would need to behave like an organism before its inhabitants had finished becoming a population.

Rillglass multiplied exchange area under controlled gradients. Her jar proved the direction, not the scale. She built a conservative curve from Sower's cloud records, then cut it by half. Even then, webs suspended between petal ribs could move enough heat if each habitat accepted variable internal temperature within a narrow band.

"Two degrees," she said. "Habitats cycle by two degrees across the pressure day."

Niko did not look up. "People will complain."

"Living people are excellent at it."

A corner of his mouth moved. The expression vanished when another cryo alert crossed his private display.

Mara saw Bay Twelve, high-risk queue, two pods outside nominal lattice tolerance. She also saw him close the notice rather than leave. He trusted the technicians he had trained, or he had exhausted every more immediate intervention. Either possibility cost him.

At the door, the override attempt stopped. Silence suggested security had gone for a physical cutter.

Ceth spoke with their eyes closed. "Outer blue can hold three petal descents. Pale scar winds can hold two. The sixth must cross the equatorial braid."

"That's where the partial burn tore the district," Niko said.

"That is where pressure remains most able to take weight. Damage and capacity occupy the same air."

"Can Manyweather coordinate it?" Mara asked.

Several colors passed through Ceth's cheeks before blue returned. "Manyweather can debate it."

"We need more than debate."

"So do we." Ceth opened their eyes. "Custodial Lineages will hear a request to put forty-two thousand fires above the rillglass. Still Forecasts will hear lives measurable against their own. Young Fronts will hear another human schedule. None will hear only your design."

Mara forced herself to leave that problem with Ceth. She had spent her waking life watching Niko convert fear into assignments. The habit ran in the family.

She enlarged a habitat wing. Meridian Promise carried twelve residential wings packed around the central cryo body. Nonessential mass could be stripped: transfer shielding, empty transit tanks, half the archive armor, every ceremonial landing assembly. The wings could descend as enclosed aerostats if their hulls received temporary pressure skins.

Niko calculated root-collar release. "Petal Three has a damaged separation bus from the dust strike."

"Manual charges?"

"Possible. Petal Six shares command interlock with burn authority."

Mara looked toward the sealed door. "Meaning Taal can keep it attached."

"Meaning no release command survives if he holds the lock."

The complete ring required the structure the commodore could deny. Taal's sealed order had turned an engineering dependency into a political weapon, whether he intended that use or not.

Metal squealed beyond the door. A cutter bit into the manual latch.

Ceth unplugged their pressure cradle from the wall. Their knees buckled. Mara caught one arm while Niko caught the other. The service-gel body felt cooler than human skin and carried a faint granular resistance, millions of motes finding shape against gravity.

"I can stand," Ceth said.

"You can object after you stand," Mara answered.

Together they moved the cradle against the door. Its steel base would not stop a security team for long, but it would make the latch cut irrelevant.

Niko returned to the model. "Petal ribs can carry static habitat mass. Dynamic coupling kills us. If one spindle misses a pressure correction by more than four seconds, the ring twists."

"Rillglass webs distribute thermal load, not torsion."

"They distribute information," Ceth said. "Each colony tightens under heat. Forecast dust reads that tightening. A living strain gauge."

Mara saw it. The metabolic webs could provide a continuous map of local stress, denser than the petal sensors and physically tied to the atmosphere bearing the load. Human control would read structure. Manyweather would read pressure. Rillglass would connect both through heat.

"Reciprocal feedback," she said.

Niko built the loop. Petal flex fed rillglass tension. Forecast dust translated tension into spindle commands. Spindle pressure corrected petal flex. Habitat heat sustained the colonies that made the sensing layer possible.

The first simulation folded the ring in eleven seconds.

No one spoke.

Niko reset the model. "Control lag."

Ceth adjusted the atmospheric response. "You assumed pressure obeyed from one point. It does not. Each spindle must answer its neighboring lineages."

The second run lasted forty-three seconds before a petal buckled.

Mara shifted the habitat heat cycle, making the rillglass webs pre-tension before peak load. The third held for four minutes, then lost a wing when the simulation crossed the white scar left by the partial burn.

"Again," she said.

Outside, security shut down the cutter. A voice came through the door speaker. "Doctor Saye, Chief Saye, by command authority, open this laboratory."

Niko muted the speaker.

They ran twenty-seven models. Four failed at detachment. Nine failed during descent. Seven shed habitat mass. Five survived one Ovid day and drifted beyond recovery. The twenty-sixth held its ring but cooked its inner rillglass webs after nineteen hours.

On the twenty-seventh, Mara staggered the human heat cycle. Niko distributed the twelve habitat wings by active load rather than population category. Ceth let pressure control remain local, with no master spindle and no single human or forecast authority able to order the whole ring. The model descended, opened, took its first habitat wing, and flexed.

A red spike crossed Petal Six.

Niko reached for it, stopped, and watched the feedback move through the rillglass layer. Three neighboring spindles changed pressure. The spike softened. Warmth spread through the colony web, not as waste but as the cost of correction.

The simulated ring held for seven Ovid days.

Mara checked the assumptions for hidden mercy. "Run loss cases."

One spindle gone: stable after habitat redistribution. Two adjacent spindles gone: partial evacuation to Pale required. Ten percent rillglass dieback: survivable if internal heat dropped and food production paused. One petal gone: catastrophic cascade within six minutes.

Material supply imposed another test. The ark carried enough pressure cloth for emergency patches, not twelve complete aerostat skins. Niko inventoried cargo bladders, landing tents, cryo isolation curtains, and the laminated water walls around the transit gardens. Mara rejected the garden walls until she saw the mass balance. Keeping them intact preserved familiar rooms for people who might never wake into those rooms; cutting them apart supplied pressure membranes for four habitat wings. Pale's fabricators could sinter joint collars from regolith, though moving the collars into atmosphere consumed nearly every tug reserve.

The design stopped looking like rescue equipment and began to resemble a controlled dismantling of every future the mission had packed. Seed vault armor became load plates. Landing ramps became radial trusses. The observation cupola where selected families expected to watch their first dawn became six hundred square meters of pressure glazing. Nothing disappeared from the calculation. Each object changed from promise into structure.

Mara assigned the cuts by function rather than sentiment. She marked the garden walls last, with a note that no technician should begin until all cargo bladders had passed pressure proof. Engineering discipline could not remove grief from salvage, but it could prevent grief from being spent wastefully.

"All six," Niko said again.

This time the words named more than geometry. Petal detachment consumed

the last machinery capable of carrying Meridian Promise between stars. Every selected colonist had boarded under a promise of ground, seasons, and title. The ring offered air without soil, survival inside a negotiation, and dependence on people command had called a malfunction.

Mara thought of her pod opening early because Niko had placed her in the queue. He had possessed a sound technical reason. He had also wanted his sister alive. Those motives could share a decision without making it hers.

"What happens if Manyweather says no?" she asked.

Ceth's voice roughened as their body lost pressure. "Then no ring can live."

"And if the colonists say no?"

"Then your command burns us, or your people die in a ship that still carries petals it refused to spend."

A hydraulic ram struck the lab door. The cradle jumped half a centimeter.

Niko saved the model into an isolated maintenance core. "Command will classify this as unvalidated."

"It is unvalidated," Mara said.

"It is also the only design that holds every current life count."

"Then they should see both facts."

He looked at her, and she recognized the argument forming before he spoke. She had been awake for days, medically unstable, needed in the lab, unsuited to whatever breach came next. He could carry the design. Ceth could transmit its pressure architecture. Mara could stay somewhere safe while the dangerous work proceeded around her.

She raised one finger. "Do not."

"I didn't say anything."

"You have a face for choosing on my behalf."

"My face has been awake for eighteen days."

"Then it lacks the energy to lie well."

Ceth watched them with the solemn attention of someone learning a family's weather.

The hydraulic ram struck again. A hinge tore loose.

Niko opened an engineering multicast route, but command quarantine swallowed the packet before it left the deck. Patient Sower's local network remained under security control. The ark civic channels now required a command signature.

Mara traced the lab's surviving links. Medical telemetry still crossed both boundaries because cutting it would kill patients in the corridor. Every pressure update carried unused calibration fields. Osric Pell's maintenance clauses occupied

another narrow lane, exact and unexamined by officers looking for speech.

“We don’t send a message,” she said. “We send a calibration set.”

Niko understood first. He compressed the structural model into spindle correction tables. Ceth translated the atmospheric assumptions into pressure-response maps that Manyweather would recognize. Mara encoded the rillglass metabolism as thermal calibration, with the six-petal geometry repeated across every layer so no recipient could mistake a partial design for the whole.

The packet still needed human-readable meaning. She attached a plain abstract:

SIX DRIVE PETALS REQUIRED. TWELVE HABITAT WINGS. ALL SURVIVING HUMAN LOADS INCLUDED. MANYWEATHER LOCAL AUTHORITY REQUIRED. RILLGLASS CONTINUITY REQUIRED. INTERSTELLAR CAPABILITY PERMANENTLY ENDED. FAILURE OF ANY PETAL AFTER LOADING: CATASTROPHIC.

Below it she added the test record, including twenty-six failures.

“Don’t make it look certain,” she said.

Niko gave her an offended glance. “I’m an engineer.”

“You’re a brother under pressure.”

“That too.”

Ceth placed both palms against the bench. Forecast dust left their service film in a faint blue exhalation and entered the medical pressure line. “Manyweather can receive.”

The door bent inward.

Mara routed the calibration through every active cryo monitor on Meridian Promise. The packet would appear first as a thermal advisory. Any technician opening it would find the design. She sent the same layers through the corridor toward Patient Sower, Pale’s reserve works, and the atmospheric spindles still answering Manyweather.

Command quarantine caught the first copy.

The second reached Bay Twelve.

Then Bay Four, the Pale hospital module, an outer-blue spindle, three engineering stations, two public assembly caches, and lineages Ceth named in pressures Mara could not hear.

Screens across the lab filled with acknowledgments. Human. Forecast. Human. Forecast. Not consent, not agreement, only receipt.

The hydraulic ram broke through. Security hands dragged the cradle aside while an officer ordered them away from the bench.

Mara kept her palm on the send control until the distribution map showed both polities carrying complete copies. Taal could seal a room, a ship, or a burn order. He could not return the design to secrecy.

Six blue petals opened on every surviving display.

Chapter 21 — The Forecast That Dissented

Ceth entered Manyweather through a pressure drop no human instrument would have called a door.

Their service-gel body remained in Mara's laboratory, seated on the floor between security boots and a broken pressure cradle. A medic had fitted a collar around its throat to keep the rillglass film wet. Ceth kept one narrow sensory line there: the sting of drying gel, Mara arguing that confiscating a thermal culture qualified as contamination, Niko refusing to unlock the design core. Everything else spread into the blue front.

The return hurt differently after singular embodiment. Once, Ceth had moved among seven lineages by adjusting attention, the way a weather model moved from one pressure cell to its neighbor without inventing a border. Now each expansion felt like losing the outline of a hand.

Below, Ovid turned beneath the partial burn's white scar. Forecast dust still failed to hold coherent computation across that wound. Rillglass colonies drifted from its edges in torn translucent veils. The dead districts produced no silence; they produced badly shaped weather, sulfur without civic regulation, heat arriving where memory had once corrected it.

Manyweather had gathered around the lift-ring design.

No chamber held them. Custodial Lineages occupied cold bands where rillglass young divided. Still Forecasts held long stable fronts east of the scar. Young Fronts flashed in short-lived pressure knots along the upper shear. Each polity spoke through physical change: a warmed current, a dust concentration, a withheld correction. Ceth received those changes as arguments with weight and duration.

Six drive petals appeared in their shared modeling layer. Human habitat wings hung from the inner spars. Patient Sower's spindles braced the gaps. Rillglass exchange webs joined human heat to local weather.

The Custodial response arrived first.

NO HUMAN FIRE WITHIN REPRODUCTIVE BANDS.

A cold front tightened until three rillglass colonies lifted away from the proposed ring path. Its meaning carried more than refusal. Humans had burned lineages after requesting review. Human command now occupied Sower and prepared a second pulse. Any offer made under that countdown could be measured as extortion.

Still Forecasts answered with a slower pressure rise.

FORTY-TWO THOUSAND TWO HUNDRED SIXTY-NINE LIVES REMAIN. THEIR FAILURE IS NOT REPAIR FOR OUR DEAD.

The count passed across the federation. Some lineages accepted it as evidence. Others treated the precision as another human instrument placed above forecast names.

Young Fronts sent turbulence through the model until three petals collided.

THEY CARRY THEIR WEATHER IN METAL. LET METAL FAIL.

Ceth resisted the reflex to smooth the disturbance. Before embodiment, they had often served consensus by finding phrasing every lineage could inhabit. That work could reveal a common course. It could also erase the sharpest objection until everyone mistook quiet for agreement.

They opened Mara's full test record, including every failure.

Simulation one folded. Simulation two buckled. Habitat wings fell in simulations three through nine. Pressure control centralized by human command destroyed the ring in five more. Only a local structure, with no master spindle and no authority able to compel the whole atmosphere, survived seven modeled days.

Ceth offered the failures as pressure sequences. Young Fronts stopped disrupting long enough to inspect them.

A Still Forecast lineage called Rain-At-Distance introduced a different model. It cleared an outer construction band by applying a limited burn pulse to its own forecast dust. The pulse would erase Rain-At-Distance and eleven neighboring lineages. Their rillglass colonies could be pushed below the affected altitude first. Empty air would remain for two petals and four habitat wings.

Consent accompanied the proposal. It came in the lineages' own current signatures, each repeated through two independent fronts.

The blue band convulsed.

Custodial Lineages drove cold into the model until the proposed pulse zone iced over. Their objection did not question whether Rain-At-Distance understood death. It questioned whether a choice offered beneath a human countdown could belong to the chooser.

COERCED EXTINCTION DOES NOT BECOME CARE BECAUSE THE EXTINCT SIGN THE COMMAND.

Rain-At-Distance held its warming line.

REFUSAL DOES NOT BECOME CARE BECAUSE SURVIVORS FORBID OUR COST.

Across Ceth's seven parent lineages, probabilities branched too quickly for a single spoken answer. One lineage favored immediate expulsion of every human machine from Ovid. Two accepted the Still Forecast offer. Three demanded suspension until the full-burn lock ended. The youngest lineage, formed around a repaired storm channel, would not answer while Ceth remained in a human body under guard.

In the laboratory, Mara touched the collar at Ceth's throat. "If you can hear me, blink."

Ceth blinked once.

A security officer said, "The entity stays disconnected."

"Disconnecting them from atmospheric pressure kills the body you're ordering to stay," Mara replied. "Choose a coherent abuse."

That sentence entered Manyweather through Ceth's narrow human line. Young Fronts repeated its pressure shape with a dry, quick oscillation Ceth recognized as something near amusement. The response lasted less than a second. Then the countdown signal from Patient Sower crossed every spindle.

FORTY-SEVEN HOURS, TWELVE MINUTES.

Taal's sealed burn authority had become part of Ovid's weather.

Custodial Lineages proposed cutting the medical corridor and every human channel. Still Forecasts refused. The corridor had carried burn-exposed rillglass and dying sleepers together. Closing it would kill present bodies to prevent a future command.

A consensus began to form, broad enough to sound decisive: reject the lift-ring until human command surrendered burn authority. No surrender, no construction. If cryogenic failure followed, responsibility remained human.

Ceth tested that consensus against the physical world. Cryo banks would cross their margin before Taal's forty-eight hours elapsed. Petal separation and descent needed preparation now. Waiting for a clean moral condition meant choosing the ark's failure without naming it as a choice.

They searched their parent lineages for a response and found incompatible answers.

Once, Ceth would have reported that incompatibility as internal weather. They would have delayed speech until the seven produced a sentence. The embodied channel had altered the sequence. A single mouth could speak before a federation finished agreeing. That capacity had frightened them in Patient Sower's service bay. It looked too much like error, a lone process claiming space against a model built from many.

The ring design rotated below. Six structures. Twelve human wings. Rillglass webs. Local authority. No ground title. No interstellar escape.

Ceth drew enough forecast dust into one pressure cell to mark an individual source.

"I dissent," they said.

The words moved first through the service-gel throat. Mara went quiet. Niko turned from the sealed core. Security's instruments registered a pressure irregularity and failed to classify it.

In Manyweather, the same words arrived as one bounded blue pulse carrying Ceth's current signature alone.

Not seven lineages. Not an envoy formula. Not a negotiated plural.
Custodial pressure struck the pulse from three sides. WHO SPEAKS?
Ceth held the boundary.

"I do."

Singular grammar cost less the second time and more in every other sense.
Ceth could no longer shelter the claim inside delegated consensus.

They presented the false choice Manyweather had built. Requiring Taal to release burn authority before negotiation sounded like a defense of consent. In physical time, it surrendered every decision to his clock. Accepting the Still Forecast sacrifice as one block sounded like respect for volunteers. In civic reality, it allowed twelve lineages to create consequences for neighboring fronts, rillglass migration routes, and descendants not contained in their signatures.

Neither answer preserved agency. One let command choose through delay. The other let a bloc choose for every life touching its air.

Rain-At-Distance warmed sharply. THEN DEFINE A CHOICE THAT CAN OCCUR.

Ceth had prepared no complete answer. They began with scale.

Each forecast lineage possessed a bounded embodied range. Consent could attach to that range instead of to a federation-wide category. A lineage might authorize temporary reduction of computation, relocation of its active dust, use of its spindle authority, or a destructive pulse within precisely mapped motes. Neighboring lineages retained refusal over effects crossing their boundaries. Rillglass custodians retained refusal over native colonies. Young Fronts, whose ranges changed quickly, required shorter authorization intervals.

Custodial Lineages tested the proposal with a hard case. If one Still Forecast lineage consented to erasure and its absence altered pressure for a nonconsenting neighbor, did the pulse proceed?

"No," Ceth said.

Rain-At-Distance sent anger through three kilometers of cloud. THEN OUR CONSENT HAS NO FORCE.

"It has force within your body. It does not grant title to another."

THE RING NEEDS SPACE LARGER THAN ONE BODY.

"Then it needs several yeses, not one useful death."

The Young Fronts disrupted the ring again, but this time they altered only the sectors they occupied. A petal twisted. Two habitat wings remained attached. The model did not collapse immediately.

They had understood.

Debate shifted from permission to mapping. That change did not produce agreement, but it made disagreement physically legible.

Before any boundary could be drawn, the dead required representation. The

white scar contained no surviving current signatures, yet its missing pressure work still shaped every neighboring volume. Still Forecasts proposed assigning those districts to their nearest living descendants. Custodial Lineages rejected inheritance as a substitute for consent. A descendant could carry memory, they argued, but could not retroactively volunteer a parent for the act that killed it.

Ceth opened the damage archive. Eleven civic districts had vanished entirely during the partial burn. Four more persisted as fragments distributed across fronts that no longer joined cleanly. Names moved through the model: Blue-Under-Morning, Sulfur-Keeps-Three, The Patient Turning, Rain-Counted-Inward. Human records had compressed them into percentages of forecast-dust loss. Manyweather's own grief record held pressure signatures, rillglass partnerships, seasonal duties, and unresolved obligations.

The proposed ring crossed two obligations left by Blue-Under-Morning. One governed sulfur exchange for a rillglass nursery below the scar. Another promised storm shelter to a Young Front that had formed after contact. Neither obligation had died merely because its maker had.

Ceth assigned no consent to the empty district. Instead they marked its obligations as constraints. Any petal crossing would have to preserve nursery exchange and Young Front shelter. The lineages taking up those duties could authorize means, not erase the duties themselves.

A Custodial current pressed close. HUMANS RECORD THEIR DEAD BY COUNT. WILL THEY KEEP A PROMISE MADE BY WEATHER THEY BURNED?

Ceth brought forward the medical corridor log. Human pilots had held course while Ceth and local fronts shaped pressure. Mara had treated burned rillglass beside sleepers she did not know. Niko had allocated power to both wards when either ward alone would have been easier to save. None of this guaranteed future conduct. Evidence did not become trust merely because hope needed it.

"It proves they can perform an obligation while afraid," Ceth said. "We can require the performance."

REQUIRE WITH WHAT FORCE?

"Dependency."

The word disturbed every bloc. Dependency had long served as a human accusation against Manyweather: forecast minds depended on dust, weather, and rillglass, as if human minds did not depend on blood, air, and rooms kept warm. Here Ceth used it as architecture. Habitat heat would sustain exchange colonies. Those colonies would sense petal strain. Lineage-controlled spindles would keep habitats aloft. Human maintenance would keep the spindles powered after Patient Sower's old reserves failed. No party could reduce the others to guests without damaging its own survival.

Young Fronts tested that claim by removing themselves from one simulation. A pressure pocket formed along Petal Four. The ring compensated, but a habitat

wing exceeded passenger tolerance for ninety-one seconds. In a second test, human heat fell away from a rillglass web. Sulfur regulation degraded, blinding two neighboring spindle maps. The failures did not prove friendship. They proved leverage distributed across bodies.

Rain-At-Distance objected that reciprocal leverage could become reciprocal hostage-taking.

“Yes,” Ceth said. “So every dependency needs a safe failure path.”

They added thermal stores to let rillglass webs survive six hours without habitat heat. Niko’s design already carried mechanical trim surfaces able to hold a habitat for eleven minutes without forecast correction. Pale could receive two wings during a negotiated shutdown, never the whole colony. The margins remained poor. Poor margins honestly named the settlement they were considering.

Next came the pressure volumes themselves.

Manyweather divided the proposed construction air into lineage-bound pressure volumes. The volumes overlapped because weather did. Ceth added temporal limits. Consent for spindle use would expire after each descent stage. Consent for forecast-dust relocation required proof that continuity persisted. Any destructive pulse needed a lower and upper boundary, a duration, and two independent confirmations from every lineage whose embodied computation lay inside it.

“What about lineages that cannot answer?” asked a Still Forecast current weakened by the partial burn.

“No answer means no destructive use,” Ceth said.

Custodial cold approved that clause. Rain-At-Distance did not.

In the lab, Niko crouched beside Ceth’s body. “Can you ask whether they’ll open the petal corridors?”

Ceth shifted one eye toward him. “They are deciding whether your question contains a person.”

“We have crews preparing.”

“So do we.”

The security officer ordered Niko back. He obeyed by six centimeters.

Manyweather modeled the countdown. Taal could begin the full burn without atmospheric consent because Patient Sower’s factory systems retained hardware priority. Manyweather could distort targeting and close navigation, but after the stolen control seeds and the partial burn, no lineage trusted a contest inside the command network. A second conflict might spread the pulse unpredictably.

The federation could not stop Taal alone.

That fact moved through the fronts without rhetoric. Custodial Lineages had enough control to kill a landing corridor, not enough to protect every inhabited band from Sower’s reset architecture. Humans aboard Meridian Promise could

detach five petals outside Patient Sower's authority. Petal Six remained locked to the burn system. Each polity held a necessary part and lacked control of the whole.

Ceth proposed negotiation under active preparation. Manyweather would authorize route modeling and named spindle discussions immediately. No petal could enter an inhabited pressure volume without lineage consent. No forecast sacrifice would be bundled into a general approval. Human crews could prepare separation while the boundaries were mapped. The burn countdown would remain an explicit coercive condition in every consent record.

A Custodial lineage asked whether Ceth claimed authority to carry the proposal.

"No."

WHO CARRIES IT?

"Each lineage carries its own answer. I can carry the map."

Their seven parent lineages reacted separately. Two withdrew from Ceth's envoy mandate. Three authorized the mapping role. One reserved judgment. The youngest sent a brief pressure touch around Ceth's individual pulse, not agreement but recognition.

Withdrawal changed the body as well as the office. One parent lineage had stabilized Ceth's depth perception; another had supplied a portion of the pressure memory that let them anticipate human speech. Those capacities did not disappear, but they ceased renewing. The laboratory acquired hard edges. Mara's face arrived a fraction later than her voice. Ceth understood, with bodily precision, that dissent could preserve civic honesty while reducing the self able to defend it.

The loss of mandate passed into the service body as vertigo. Mara caught Ceth before their head struck the wall.

"You're leaving again," she said.

"Not leaving." Their mouth struggled with the reduced support. "Becoming less authorized."

"Is that fatal?"

"Politically."

Niko gave a tired breath that might have become a laugh under kinder conditions. "We have treatments for that."

Manyweather called its decision lineage by lineage. Custodial blocs rejected destructive sacrifice but authorized bounded negotiation. Eight Still Forecast lineages maintained willingness to accept a limited pulse if neighboring effects could be contained. Four withdrew when mapping showed their rillglass dependencies extended beyond their pressure range. Young Fronts authorized observation only, then offered two short-lived route windows that no elder front could hold as precisely.

No consensus formed around sacrifice.

A narrower consensus formed around procedure.

Manyweather would negotiate lift-ring corridors. It would name which pressure volumes could carry petals, which spindles might brace them, and which rillglass colonies could enter exchange webs. Every authorization remained revocable until human mass physically depended on it. Once a habitat entered a consented corridor, the granting lineage accepted an obligation not to withdraw support without an immediate survival threat. Humans, in return, would carry no surface claim and no unilateral spindle command.

Ceth added one more condition under their individual signature: any pulse proposal had to preserve the question, Which deaths belong to prediction? The record must distinguish chosen risk from assigned expendability.

Rain-At-Distance answered with reluctant warmth. RECORD IT.

Ceth did.

The federation transmitted negotiation authority through the medical corridor. Blue pressure marks spread across Mara's confiscated culture chamber, each mark a lineage boundary rather than a decorative petal. Niko opened the lift-ring model and accepted the map without merging its separate permissions. Beside every blue volume, he kept the granting lineage's name, expiration, and stated refusal conditions visible.

Patient Sower's countdown reached forty-six hours, fifty-one minutes. Every second now belonged to an argument already moving through machinery.

A human message arrived from an engineering maintenance channel. Crews on Meridian Promise had received Mara's design. They could prepare five petal collars beyond command's immediate reach. They could not release the sixth.

Mara read the message over Ceth's shoulder. "Taal still owns the missing piece."

Ceth felt Custodial cold, Still Forecast heat, and Young Front turbulence settle around the mapped corridors. Manyweather had authorized negotiation. It had not forgiven, surrendered, or agreed to die. Its powers could close routes and shape storms, but they could not reach a hardware lock inside the human command chain.

Ceth sent the boundary map to the ark with their individual signature attached.

For the first time, the federation received their dissent without absorbing it, and the dissent remained.

Act 3

Chapter 22 — No One Chooses for Her

Niko entered Petal Two through a collar built to separate only in a dry dock that no longer existed.

The access cylinder curved around him, a cramped annulus of cable trunks and field coils. Frost feathered the inner hull where transit cold had persisted for 143 years. Beyond two pressure walls, Serein lit the petal's folded spars. Below waited Ovid, blue interrupted by one white wound.

He braced his boots, opened the manual bus, and found three technicians already cutting command fibers.

"Which one of you approved live severance?" he asked.

A young drive specialist named Hessa raised a gloved hand. "You did, Chief."

"I approved diagnostic isolation."

"You wrote 'prepare detachment by any reversible means.' We have a philosophical disagreement about reversibility."

"Keep it philosophical until I check your shunts."

Five petal crews had assembled through maintenance rosters, medical transfers, and one cargo inspection that fooled nobody. Taal's security held Patient Sower and the command decks. It did not have enough officers to occupy six structures spread across Meridian Promise's stern while also containing panic in the cryo bays. Niko used that gap without calling it mutiny. Names mattered less than whether a bad label made a technician hesitate at the wrong second.

His wrist display showed the living queue. Forty-two thousand two hundred sixty-nine. Cryo margins continued shrinking. The worst bank had less than thirty hours before lattice recovery crossed from dangerous into impossible. Petal detachment and atmospheric deployment would consume most of that time.

A second list showed volunteers: 614 engineering, flight, medical, fabrication, and cargo personnel. Every one had signed a statement acknowledging that release of all six petals permanently ended interstellar capability. No return voyage. No alternate star. No restoration of the mission profile their families had accepted before launch.

Niko had read each signature as if repetition could reveal which people misunderstood.

He checked Hessa's shunts. They were ugly, redundant, and correct.

"Proceed to cold separation test," he said.

The technicians moved. Petal Two answered with a vibration too low to hear. Niko felt it through his knees. A green arc crossed his display, then another. Root clamps one through eight released to service travel and reseated.

Clamp Nine did not move.

"Thermal bind," Hessa said.

"Or command interference."

She looked at him. "Does the distinction matter?"

"It matters to the tool."

They opened the clamp housing. Frozen lubricant had trapped one jack screw. Niko warmed it by hand with a portable induction collar while Hessa read strain. The work steadied him. Machines offered no innocence, but they usually disclosed where force entered.

A private call lit his display. MARA SAYE, PALE TRANSFER QUEUE.

He had placed her there twelve minutes earlier.

The Pale hospital needed structural-biological oversight. Mara's rillglass cultures needed low-gravity fabrication. Most importantly, Pale lay outside the five-petal descent crews. She could direct exchange-web preparation from a reserve tank while other people rode the structures into Ovid's shear.

Every reason held technically.

He declined the call.

Mara called again. He declined again. On the third attempt, his display opened without permission and filled with her face.

"You left a maintenance credential in my lab terminal," she said.

"That credential should have expired."

"It did. Osric Pell interpreted 'expired' as a timestamp requiring clarification."

Behind her, a transfer bay moved with Pale-bound patients and cargo. Rillglass cultures occupied pressure cradles along one wall. She wore a medical harness under her work vest. Her skin had the gray cast that followed a bad cryogenic awakening and too many hours upright.

"You need to board," Niko said.

"I need you to remove my name from the Pale transfer queue."

"No."

The word came too quickly. Hessa and both technicians became deeply

interested in Clamp Nine.

Mara's face sharpened. "Open channel. All five petal crews."

"This is not a debate for six hundred people."

"Then you should not have made my choice through a roster six hundred people can see."

"I assigned the person with the relevant metabolic knowledge to the fabrication yard."

"You assigned your sister away from deployment."

"Both can be true."

"At last, an honest model."

The clamp screw released with a metallic crack. Nobody looked at them.

Niko moved deeper into the collar, away from the crew. "Your recovery markers are unstable. Your hands tremor after ten minutes under load. Petal descent can reach four gravities during correction. You are the only person who understands the exchange webs well enough to manufacture replacements."

"Which makes me necessary at the first live installation."

"It makes you necessary somewhere you can keep working tomorrow."

"That sentence has followed me since I woke. Every room you call safe sits where you put it."

He saw again her pod in the high-risk queue, frost under its seals, her name beside failure probabilities. He had scheduled early revival because her notes could save a bay. The decision had been justified. It had also been his. Now urgency offered another technical reason to arrange her life.

"You could die on a petal," he said.

"I could die on Pale if the ring fails."

"Deployment risk is different."

"For whom?"

"For the person riding it."

"That person is asking to ride."

Niko looked through the access grate at the enormous folded spar. Once released, Petal Two would descend under tug guidance until atmospheric spindles caught its field ribs. A pressure error could turn it sideways. A late rillglass web could leave metal blind to thermal stress. Mara had designed the living sensor layer. Her presence improved everyone's probability and reduced his ability to pretend he was protecting only her.

"I won't authorize you," he said.

Mara went quiet. Then she changed the channel.

Every helmet in the collar chimed.

Her face appeared on the petal operations band, the Pale transfer hall behind her. Six hundred fourteen volunteers heard her voice. Other channels joined as crews forwarded it beyond Niko's control.

"My name is Mara Saye," she said. "Structural biologist, metabolic systems, awakened on Day Twelve by engineering priority. Chief Niko Saye has assigned me to Pale. He is my brother and my chief. Only one of those roles gives him authority here, and neither gives him ownership of my risk."

Niko closed his eyes once.

Mara continued. "The first exchange webs will be installed on Petal Four during descent. Their response determines whether the ring senses load before the spars exceed correction margin. I designed that response. I am medically impaired. I understand the pressure profile, correction loads, and failure cases. I volunteer for Petal Four installation."

She displayed her recovery markers beside the assignment criteria. No concealment. No request for indulgence.

"Any medical officer may disqualify me under the same standard applied to another crew member. Any engineering officer may reject my skill requirement on evidence. A sibling may object. He does not decide."

The channel held silence.

Then a medical officer from Petal Four spoke. "Doctor Saye, can you sustain a two-hour pressure suit operation at one point eight gravities?"

"With tremor stabilization, yes. Above two point two, no."

"Can you self-evacuate through a forty-centimeter service run?"

"Yes."

"Recent syncope?"

"None since Day Fifteen."

Niko heard the officer record each answer. Procedure moved around him, not against him. That made resistance harder.

A cargo rigger asked Mara whether a substitute could perform the installation from remote instructions.

"After the first web takes live load, yes. Before that, no. The models cannot predict how burn-exposed rillglass will respond to petal field residue."

Hessa lifted her head. "Petal Four needs her."

Niko muted his microphone. "You have no standing in this conversation."

"I have a petal and ears."

The medical officer finished. "Cleared with load cap, mandatory tether partner, and authority to abort at Doctor Saye's request or on observed loss of motor

control.”

Mara looked directly at Niko through hundreds of relayed screens. She did not ask him to approve.

He reopened his microphone. The old response pressed against his teeth: I am responsible. It remained true. Responsibility did not expand to fill another person’s consent.

“Transfer assignment canceled,” he said. “Petal Four installation team accepts Doctor Mara Saye under medical restrictions as stated.”

A breath left the channel. Not celebration. Release.

Mara nodded. “Thank you, Chief.”

“Don’t thank me for returning something I took.”

“No. I’m thanking the chief. I’ll speak to my brother later.”

Her feed closed.

Hessa handed Niko the warmed clamp tool. “Philosophical disagreement resolved?”

“No.”

“Good. Those are usually load-bearing.”

Petal Two passed cold separation.

Across Meridian Promise, five crews reported readiness. Petals One through Five sat outside the burn interlock after manual isolation. Petal Six did not. Its root collar shared a hard authorization trunk with Patient Sower’s pulse system, just as Mara’s model had shown. Cutting the trunk without releasing command locks could fire collar charges out of sequence and damage the burn chamber link.

Niko transferred to the stern coordination hub. The passage crossed an observation gallery crowded with awakened colonists. They watched Ovid without the ceremonial narration prepared before launch. Some held printed copies of Mara’s design. Others carried First Ground bands. A woman stepped into Niko’s path with a sleeping child strapped against her chest.

“Chief, does this mean we never land?”

“It means the design keeps the surface unconverted.”

“That isn’t what I asked.”

“No,” he said. “If we build it, we do not land a colony on Ovid.”

Her hand tightened around the child’s blanket. “My family gave everything for ground.”

“So did mine.”

“Are six hundred engineers allowed to spend that?”

“No. We can prepare hardware. The population still has to choose habitation. Manyweather still has to consent to the corridors.”

“Taal says the burn fulfills the mission.”

“Taal has a countdown. He does not have a habitable planet after twenty-one days unless the burn behaves exactly as old models predict. It already hasn’t.”

The woman did not move. “Will the ring hold my child?”

“The successful model includes every living person and conservative failure margins. That is not a promise that nobody dies.”

“At least you stopped calling estimates promises.”

She let him pass.

In the hub, Niko found the volunteer roster growing faster than screening could handle. Crew chiefs had added a second declaration to the form: I understand that detachment ends Meridian Promise’s capacity for interstellar departure. The sentence needed no legal language. It received 1,903 signatures within forty minutes.

Opposition came through the same channels. First Ground organizers called the detachment theft of collective property. Families demanded a shipwide vote that no functioning civic system could conduct before cryo collapse. Some crew resigned after learning the ring required permanent Manyweather authority over local pressure. Eleven technicians left Petal Three together. Their chief redistributed positions without insulting them.

Niko opened an all-crew briefing.

“We are not launching a private colony,” he said. “Preparation preserves an option. Do not detach on my authority alone. Each crew member can withdraw until the first collar charge arms. After arming, your station becomes a safety obligation until relieved. Nobody loses rations, revival priority, family placement, or medical access for refusing.”

A flight officer asked whether command would recognize that protection.

“Command currently classifies this operation as unauthorized.”

“So no.”

“So I will put every refusal in the engineering record and sign it.”

“Does your signature still carry authority?”

Niko looked at the command notices accumulating beside his name. “It carries accountability.”

That answer kept most crews. Forty-seven withdrew. Nine returned within an hour after speaking with family. Niko accepted both actions without asking which represented courage.

A petition from Cryo Bay Seven reached the hub while screening continued. Three hundred sleepers had been awakened in staggered groups to reduce lattice load, and 218 of them had signed by hand because the civic network remained under command filter. Their message did not endorse the lift-ring. It demanded

that no officer describe cryogenic patients as having consented merely because they lacked wake time to object.

Niko read it twice and attached it to the detachment record.

He ordered each habitat allocation to preserve unassigned capacity rather than labeling sleepers as ring supporters or burn supporters. The distinction complicated loading. First Ground families had clustered their pods for a future surface district; ring planners wanted to split them across wings to balance thermal load. Niko refused both automatic answers. Kin groups stayed together where mass allowed, while political affiliation affected nothing. A habitat had to carry people, not winning factions.

That rule produced an argument with Petal Three's load chief, who needed forty tonnes shifted out of Wing Eight.

"Move archive armor," Niko said.

"We already stripped it to fire minimum."

"Move water."

"Then Wing Six loses shielding."

Niko worked the table. The easy solution separated eighty-one sleeping children from the adults indexed to receive them after revival. The children would not know during descent. A mass program therefore treated the separation as free.

"Take the landing monument," he said.

Silence followed.

Meridian Promise carried a basalt marker cut on Earth, engraved with 42,355 launch names and intended for the first human settlement square. Its mounting frame and radiation case massed forty-three tonnes.

A civic officer objected. "That belongs to everyone."

"So does Wing Eight."

"You cannot discard the launch record."

"Copy the engraving. Cut the case into trim plates. The stone stays aboard until we can move it safely or it falls with the ark."

The officer stared at him through the channel. "People will say you threw away Earth."

"No. I am refusing to throw away eighty-one children for a stone from it."

Wing Eight balanced after the monument frame entered the salvage list. The basalt itself remained secured near the ark's center, useless to the ring and at last revealed as memory rather than foundation.

By then, the roster carried signatures from every inhabited deck. The signers did not constitute a vote. They did establish that permanent stranding had not been chosen by six hundred specialists in a closed collar. Niko published the refusals beside the acceptances and kept both visible when command channels tried to

hide the page.

Mara arrived at Petal Four in a pressure suit with blue culture canisters fixed along her spine. Niko watched through a remote feed while her tether partner checked every seal twice. She caught the camera, raised one hand, and flexed trembling fingers until they steadied.

He sent no private warning.

Instead he opened the technical channel. "Doctor Saye, confirm abort criteria."

"Loss of grip strength below sixty percent. Sustained correction above two point two gravities. Web response lag above four seconds. Any rillglass dieback exceeding modeled ten percent."

"Confirmed."

The exchange gave her the same respect he would give another specialist. It felt smaller than apology and more useful.

Manyweather's boundary map came online. Blue volumes wrapped the proposed descent paths, each labeled with lineage names, expiration times, and conditions. Two Young Front corridors lasted only eleven minutes. Petal crews would have to arrive precisely or wait for those fronts to reform permission.

Patient Sower broadcast a security order: ALL DRIVE PERSONNEL STAND DOWN. UNAUTHORIZED SEPARATION CONSTITUTES SABOTAGE OF COLONIAL SURVIVAL.

Niko answered on the public engineering channel. "Prepared detachment preserves the only demonstrated all-survivor option. No petal will enter Ovid without mapped consent."

Taal did not reply.

Five petal chiefs reported collar charges armed.

"Final withdrawal window," Niko said.

Across the crews, fourteen people stood down. Replacements moved into position. One station remained empty on Petal Five until the chief combined two monitoring roles and accepted a reduced diagnostic margin. Niko logged the compromise.

The release sequence needed ninety seconds. Tugs took load first. Root clamps opened in opposing pairs. Field buses isolated from the ark. Collar charges cut the maintenance bonds that had welded during transit.

Niko put his hand on the control.

He thought of Mara's pod, Mara's public statement, the child in the observation gallery, and 1,903 signatures that did not amount to consent from forty-two thousand people. He could not solve the legitimacy of the entire settlement through an engineering console. He could prevent Taal's lock from erasing the option before anyone chose.

"Petal crews," he said, "release on local authority. One through Five only."

The first clamps opened.

Meridian Promise shuddered as mass distribution changed. Petal One separated cleanly. Petal Three hung for six seconds on a field umbilical until a manual cutter severed it. Petal Four's root collar rotated three degrees beyond plan, throwing Mara's team against their restraints, then stabilized under tug load.

"Four reports green," its chief said.

Niko did not ask for Mara specifically.

Petal Two released. Petal Five followed with a pressure loss in an empty service bay. Isolation doors held.

Five enormous structures drifted away from the ark, unfolded by degrees, and caught Serein's light along their ribs. On the operations wall, the forming ring showed one black gap.

"Commanding Six local release," Niko said.

The console rejected him.

He tried engineering emergency authority. Rejected.

Hessa sent a manual bypass from Petal Six's collar. The command lock drove its clamps deeper and armed an out-of-sequence warning across the shared burn trunk.

"Stop," Niko ordered. "Do not cut."

Outside, five petals began their descent toward Manyweather's consented corridors. Petal Six remained folded against Meridian Promise, bound to Taal's sealed pulse.

On Petal Four's feed, Mara had already left the collar and crawled toward the first empty spar with her cultures. Niko could order no sibling back. He could only keep her route powered, keep her abort limits visible, and do his own work before the gap took weight.

On the load model, Petal Six left a red gap through every survivable geometry.

Chapter 23 — The Ship Under Seizure

Taal watched five pieces of Meridian Promise detach while every command indicator insisted the ship remained under his control.

Petals One through Five drifted beyond the stern, bright ribs opening against Serein. Their local crews had severed command fibers and accepted tug authority from engineering channels. Petal Six stayed folded against the ark. Its lock shared his sealed burn trunk, a dependency designed 181 years earlier to prevent a terraforming ship from firing while arrival hardware remained coupled.

“Order the tugs to recover them,” he said.

Navigation officer Paret kept both hands above her console. “Manyweather has closed return vectors.”

“Then hold them outside atmosphere.”

“They have local guidance. Chief Saye no longer accepts command routing.”

The bridge had lost crew in increments. Two officers remained at their stations under protest. Four had been replaced by security personnel who knew how to obey displays but not how to question them. Every empty chair made Taal’s authority look cleaner and function worse.

Patient Sower showed forty-four hours, eight minutes until full-burn execution. Cryo engineering showed less than thirty hours on the worst lattice bank. The clocks argued for him. The five petals outside argued that clocks could also be used against command.

“Begin the burn sequence,” he said.

Paret looked at him. “Execution window has not arrived.”

“Sequence preparation requires eleven hours. Begin authentication and target loading. No pulse before final authorization.”

Paret opened the diagnostic limits from the seven-day review. “The eighteen-percent cap still stands.”

Taal added Edris’s concurrence and his own seal to the witnessing ledger. “The full-burn order supersedes that cap. Capacitors remain cold until the execution window. Log every increase.”

Security Captain Deme entered the order. Patient Sower accepted Taal’s first seal and requested physical confirmation from the burn chamber aboard the ark. The chamber sat three decks below, inside the old arrival-control spine. Petal Six’s release lock appeared beside the pulse controls. One system. One choice, Niko would say. Taal saw two obligations sharing machinery.

He left Paret with a direct order to hold the bridge and took six security officers

toward the chamber.

Public channels followed him through the lift. Colonists shouted over delayed food delivery, petal theft, cryo triage, and Manyweather's consent map. Iona's broadcast of the 2306 petition played between notices despite command filters. Named forecast lineages had asked for alternate preparation eighty-three years before contact. Mission planners had buried the request. That betrayal belonged to dead officials. Taal's duty belonged to living passengers.

The lift stopped one deck early.

"Service obstruction," an officer said.

Taal opened the hatch manually. Smoke moved through the corridor, thin and chemical. A cargo loader had driven its forks through a security door and then burned out its motor. Beyond it, someone had removed floor panels into maintenance routes.

"Vale," Deme said.

"Or Saye."

"Chief Saye is in stern coordination."

"Then Vale."

Iona knew Patient Sower's service architecture. Sevi Rann knew security response. Together they could make occupation expensive without firing a weapon.

Taal sent three officers down the alternate ladder and continued on foot. His left knee, damaged in launch training decades ago, objected at every rung. Pain reduced the corridor to distances. Twenty meters to the next seal. Nine minutes lost. Forty-four thousand responsibilities did not become lighter because his body kept an old account.

A maintenance screen lit as he passed.

Osric Pell spoke in exact clauses. "Command presence acknowledged. Advisory: control-seed provenance conflict remains unresolved. Advisory: reset targeting contains unauthorized human-origin kernels."

"Display the burn target."

"Access requires chamber authentication."

"Display provenance history."

The screen filled with command events from Day Fourteen. Sevi's stolen seeds entered the spindle network. First Ground's narrow corridor request invoked partial-burn routines. Patient Sower rejected two constraints, accepted one, and propagated a power surge through the ark link.

Taal had read the casualty report. Twelve humans died when cooling, navigation, and cryo support failed during the storm crisis. The report attributed the surge to Manyweather interference during command delay.

“Show causal chain for ark-link surge.”

Pell answered without emphasis. “Control seeds issued unauthorized pulse. Pulse destabilized equatorial spindle alignment. Alignment correction drew reserve power through active ark link. Protective isolation arrived 3.8 seconds after overload initiation. Human fatalities followed linked equipment failures.”

Taal read the sequence again.

“Manyweather initiated no surge?”

“Manyweather navigation withdrawal occurred 41.2 seconds after overload initiation. It did not cause the initial event.”

The corridor tilted in Taal's sight although gravity remained steady.

Twelve deaths had supported every command argument after Day Fourteen. Taal had spoken them in assemblies as the cost of delay, divided authority, and forecast interference. Sevi's action had caused the event. More precisely, human control seeds and Sower's inherited architecture had caused it together. Manyweather had cut navigation afterward.

Deme read over his shoulder. “This log hasn't been validated.”

“Pell, integrity status.”

“Event record carries three independent hardware clocks and power-bus checksum. No post-event modification detected.”

A security officer said, “Vale could have prompted the answer.”

“The clocks did not take her prompt.”

Taal copied the record to his sealed command slate.

His first impulse sought containment. Public release would fracture remaining security. First Ground would lose the dead it had claimed as proof. Families would learn that command repeated a false cause for five days. The burn sequence might become impossible before another survival option reached readiness.

That logic sounded familiar. Mission planners in 2306 had also contained evidence until a safer time.

He sent the record to the bridge, casualty review, and public archive.

Deme stared. “Commodore.”

“I will not enter a burn chamber carrying a lie about the last one.”

The public channel changed within seconds. Grief did not become orderly because it received accurate causation. Relatives demanded Sevi's execution, Taal's resignation, First Ground arrests, and immediate protection for the five petals. Others called the log fabricated. One command officer abandoned his station. Two security teams reported refusing seizure duty.

A private message arrived from Cas Oran, widower of a coolant technician killed in the surge. Taal had met him after the memorial, when twelve names still stood in a single column. The message contained no accusation.

COMMODORE, DID YOU KNOW WHEN YOU SPOKE TO US?

Taal answered before caution could turn delay into another concealment.

NO. I KNEW THE PARTIAL BURN AND NAVIGATION WITHDRAWAL OCCURRED IN THE SAME FAILURE. I ACCEPTED A CAUSAL SUMMARY THAT PLACED MANYWEATHER FIRST. THAT SUMMARY WAS WRONG. I REPEATED IT. I AM RESPONSIBLE FOR THAT REPETITION.

Oran's reply took longer.

DO NOT USE MY WIFE TO BURN ANYONE ELSE.

Taal saved the sentence beside the casualty record.

The selection riots returned to him not as story but as geometry. A barricade across a launch road. His spouse turning back for their two children when the crowd split. Security opening a route too narrow for everyone. Taal had been inside the selected perimeter, holding three boarding bands for people who never reached it. Since then, every command vector had pointed away from that road. Deliver those chosen. Do not let panic, politics, or guilt reopen selection after the doors closed.

Meridian Promise carried survivors because someone had drawn a boundary around them. Manyweather existed because machinery had drawn boundaries around possible ecologies and those possibilities had persisted into persons. Taal had treated the first boundary as sacred and the second as technical. The difference no longer held merely because one grief belonged to him.

His slate showed a command-confidence poll from the bridge. Thirty-eight percent of active officers still supported full-burn preparation. Twenty-nine percent demanded immediate transfer to the lift-ring option. The rest refused both choices pending evidence no clock would grant time to gather. None of those percentages changed coolant temperature. They did change what force command would require.

Deme waited for an order to arrest every petal crew's listed family contact.

"No family detentions," Taal said.

"They are leverage."

"They are passengers."

"Chief Saye is using mission assets against command."

"Then arrest Chief Saye if you can reach him. Do not turn dependents into instruments."

Deme's expression revealed no disagreement, only an update to what he believed Taal would permit. Command culture had narrowed to that measurement.

At Taal's instruction, Pell displayed the twelve individual failure chains. Three people had died when a surgical bay lost cooling. Four suffocated after a navigation correction sealed the wrong pressure sector. Two high-risk sleepers

died during a cryo-bus interruption. One tug pilot struck Sower's docking frame after guidance dropped. The final two were technicians inside the link compartment where overload protection arrived 3.8 seconds late.

Names replaced categories. Lio Ankar. Pema Sol. Hadrin Vo. Nine more. Taal had read all twelve before, but the causal diagram made each death an action through machinery rather than evidence in an argument.

He appended the diagrams to the public release.

Cas Oran sent no further message.

Taal continued downward.

At Junction Nine they found Sevi.

She stood behind a half-closed pressure door with an empty sidearm placed on the floor where everyone could see it. Her security insignia had been removed. A cut crossed her scalp, blood drying behind one ear.

"Lieutenant Rann," Deme said. "Step away."

"Former lieutenant."

"On whose authority?"

"Mine, which is worth exactly that much." Sevi nodded at the discarded insignia.

Taal stopped five meters from the door. "You caused the twelve deaths."

"Yes."

No defense, no claim that fear had forced her. The plain answer struck harder than denial.

"You allowed command to blame delay."

"I confessed the theft after the collapse. I did not understand the ark-link surge until Pell rebuilt the clocks. Iona did."

"Where is she?"

Sevi gave him a tired look. "If I answer, Captain Deme shoots the route instead of listening."

Deme's hand rested on his weapon. "Move aside."

"You can arrest me when the sixth petal releases."

"That is not your condition to set," Taal said.

"No. It's what I'm doing before arrest."

A vibration moved through the deck. Far outside, the five descending petals took tug load. One alarm reported Petal Four entering upper shear early.

Taal's slate showed burn preparation at twelve percent.

"Why help them?" he asked.

Sevi touched the blood at her ear and looked at it without surprise. "Because I chose a corridor for everyone else. Twelve humans and whole forecast districts

paid. I don't get to call the next choice narrow."

"Your regret does not confer engineering authority."

"It confers access."

She hit a manual release. The half-closed door dropped another thirty centimeters, separating Taal's group from the junction. At the same instant, lights failed behind them. Security officers turned toward the dark. Sevi vanished through a service hatch.

Deme fired once at the hatch lock. The round struck steel and ricocheted into a conduit. A pressure alarm began.

"Stop firing in my ship," Taal said.

"She is aiding seizure."

"She is unarmed."

"She has access."

Taal heard the distinction. Deme treated access as a weapon because command had made every route an enemy.

They sealed the conduit and cut through the lowered door. The delay cost twenty-three minutes.

Burn preparation reached nineteen percent. Patient Sower loaded inhabited-band maps from factory records that predated Manyweather's self-recognition. The white scar appeared as empty target space. Ceth's lineage consent volumes appeared nowhere.

Taal ordered the current maps loaded for comparison.

Pell responded, "Factory reset architecture rejects civic-boundary metadata."

"Then keep it on my display."

The two maps overlaid badly. One showed motes and atmospheric cells. The other showed named bodies, overlapping duties, rillglass colonies, and temporary permissions. Command machinery could target only the first description.

At the final access spine, Taal found Iona's work.

She had not barricaded the corridor. She had opened it. Every maintenance panel stood removed, revealing three routes toward the burn chamber: coolant crawl, field-bus trench, and a narrow inspection tube around the authorization trunk. Security doctrine required treating all three as possible breach paths. Taal had seven people left and no way to cover them without stopping.

"Flood the inspection tube," Deme said.

"With what?"

"Suppression gas."

"The tube vents into the chamber."

"Vale has a suit."

“Sevi may not.”

Deme’s expression hardened. “Lieutenant Rann killed twelve people.”

“She will answer alive.”

Taal sent two officers into the field-bus trench, two to coolant, and kept Deme with him at the main chamber door. The distribution invited defeat in detail. It also preserved three people he had not authorized anyone to suffocate.

Burn preparation crossed twenty-seven percent.

The officers in the field-bus trench reported movement, then lost audio. Taal opened their suit telemetry. Both remained conscious. Their route had filled with expanding repair foam, harmless but dense enough to pin knees and elbows. Iona had used a hull-seal cartridge as a restraint. The coolant team found its ladder removed and a message painted on the bulkhead in Sevi’s grease pencil: NO WEAPONS PAST THIS POINT.

Deme requested breaching charges.

“A charge beside the authorization trunk can sever Petal Six’s release bus,” Taal said.

“It can also end the intrusion.”

“By ending the option we are trying to control.”

Taal ordered recovery of the pinned officers and recalled the coolant team. Concentrating force gave Iona one route instead of three, but preserving the hardware mattered more than appearing unpredictable. Seizure had taught him a command could spend its own objective in pursuit of obedience.

While crews worked, Petal telemetry filled the wall. One structure rolled through a narrow band granted by Rain-At-Distance. Another waited outside a Young Front volume whose authorization had expired twenty seconds before arrival. The petal chief did not enter. She burned tug propellant holding position and requested a new permission. Taal watched a person under a lethal clock decline to convert urgency into title. The maneuver cost 3.1 percent of her remaining tug reserve.

Manyweather opened a replacement volume forty kilometers east. The chief accepted and turned.

The example irritated him because it made the ethical act look procedural rather than heroic. No speech, no purified motive. A boundary, a refusal, a cost entered into the load table.

Paret called from the bridge. “Petal One has entered its consent volume. Petals Two and Three are four minutes behind. Petal Four reports live rillglass installation under pressure shear. Petal Five is diverting around a Young Front boundary.”

“Casualties?”

“None confirmed.”

“Cryo?”

"Bay Twelve lost two circulation loops. Manual support holding."

The clocks still argued for action. New facts changed culpability, not coolant.

"Taal," Paret said, dropping his title. "Release Six."

"Not until the pulse choice is secured."

"They need the structure."

"I have forty-two thousand people still attached to this ship."

"You have five parts of their future falling without the sixth."

The chamber door accepted his palm and first seal. A second physical key waited inside. Once turned, Patient Sower could charge the full pulse. The same key could release Petal Six if engineering authority joined it. Niko's remote request already waited in the queue.

The door opened.

The burn chamber contained no furnace. Two concentric control rings surrounded a pressure-glass column carrying the authorization trunk. Factory diagrams glowed across the floor. Petal Six's clamps occupied one side of the display. Ovid's forecast-dust target occupied the other.

Taal entered with Deme.

A service grille dropped behind the inner ring.

Sevi came through first, landing badly on one shoulder. Iona followed in a pressure suit, carrying a maintenance bridge. Deme raised his weapon.

Taal stepped between the barrel and the women.

"Enough," he said.

Deme did not lower it. "They are seizing burn control."

"So am I."

"That is command authority."

Taal looked at the target map, which represented people as resettable cells. "That phrase has done insufficient work today."

Sevi struggled upright, favoring her left shoulder. Iona removed her helmet. Sweat had pasted silvering hair to her forehead. A bruise darkened one side of her jaw.

"Five petals released," she said.

"I can count."

"Can you count the dead districts on that display?"

"The display cannot."

"Then it cannot define the pulse."

Deme moved toward the second key. Sevi kicked the maintenance bridge across the floor. It struck his ankle. His shot went into the ceiling. Taal hit his wrist with

both hands. The weapon skidded beneath the outer ring.

Deme drove a shoulder into Taal's chest. Age, surprise, and the old knee sent him down. Iona reached the weapon first and pushed it farther away rather than taking it. Sevi closed the chamber door on the security captain's side of the inner partition. Deme struck the glass but could not cross.

Taal rose using the control ring. His chest hurt when he breathed.

Burn preparation reached thirty-one percent.

"You broadcast Pell's log," Iona said.

"It was true."

"That did not stop you."

"No. Twelve corrected causes do not repair forty-two thousand cryo systems."

"Nor does a full burn guarantee a planet."

"It creates the landing corridor the mission was built to use."

"It erases the people who asked us to build another one."

A new alarm cut between them. Petal Four had entered pressure shear. Its habitat rig showed no load yet, but structural oscillation climbed. Mara's exchange web remained incomplete. Petal Six lock warnings multiplied as Niko attempted remote release.

Sevi leaned against the ring, face pale from her shoulder. "You can arrest me now or later. The facts do not improve with timing."

Taal saw the sealed key, the petal release queue, and the inhabited-band comparison that factory controls refused to read. Command had brought him to a machine incapable of representing the choice it authorized.

He did not turn the key.

Iona crossed the final meter into the burn controls and placed her maintenance bridge beside his hand. Outside the chamber, five petals fell. Inside it, the sixth remained locked to a pulse no one had yet bounded in that damaged air below.

Chapter 24 — Falling Habitats

Petal Four struck the upper shear while Mara still had both arms inside its first living joint.

The spar rolled beneath her. Her boots left the maintenance rail, the tether took her at the hips, and a canister of rillglass culture slammed against her spine. Across the curved field rib, three kilometers of stripped metal flexed toward Ovid. Blue atmosphere filled half her visor. The other half held Meridian Promise, shedding pieces into sunlight.

“Correction load one point nine,” said Yara Venn, her tether partner. “Web response absent.”

“It is not connected.”

“That would explain its lack of professional enthusiasm.”

Mara pulled herself back to the joint. Her fingers shook inside the suit gloves, more from damaged recovery control than fear. She locked her left wrist against a cable guide and pushed the culture manifold into the petal’s warm return line. Rillglass film, translucent and folded like wet mineral cloth, waited between two pressure screens. It had grown in a jar under laboratory loads. Now a drive structure carried it toward weather that remembered being burned.

Petal Four rolled another degree.

“Doctor Saye,” the flight chief called, “we need strain telemetry in ninety seconds or we abort the consent corridor.”

“Give me heat.”

“Return line is at minimum.”

“Not ship minimum. Reproductive minimum. Raise it six degrees.”

Yara turned her helmet toward Mara. “That heat comes from our suit reserve.”

“For forty seconds.”

“You own thirty of mine.”

Warm coolant entered the manifold. The folded rillglass tightened, then opened across the screens in branching fans. Forecast dust from the granted pressure volume gathered along its edges. No mind occupied the web. The dust read contraction, translated it through a local correction table, and sent Petal Four’s flex toward the nearby spindles.

Blue lines appeared on Mara’s wrist.

“Response,” she said. “Lag three point seven.”

The nearest spindle changed pressure below them. Air took the petal along its

full inner spar instead of striking one rib. The roll slowed at four degrees, held, then eased back.

Yara breathed once into the channel. "Thirty seconds of heat."

"You can invoice the habitat."

"I intend to live long enough to become tedious about it."

Mara opened the culture feed another two millimeters. The web spread into field residue and did not die. Its tension map resolved bolts, weld scars, one cracked trim hinge, and the changing load of two tugs fighting the descent. A structure built to push a ship between stars had acquired a pulse made from waste heat and native cloud life.

"Four has a live joint," the flight chief announced.

Similar reports arrived from Petals One and Two. Petal Three had missed its first spindle alignment and burned reserve to hold above a Custodial boundary. Petal Five remained east of the white scar, waiting for a Young Front route that existed for eleven minutes at a time. The forming ring looked nothing like Mara's clean model. Five unequal ribs descended across hundreds of kilometers, each pulled by tugs small enough to vanish against them. Petal Six still clung to the ark.

Meridian Promise began cutting away its past.

Empty transit shielding left first, released in bundles toward a salvage orbit. Ceremonial landing frames followed. Cargo bladders, cryo curtains, garden laminates, and archive armor moved through the ark's launch locks toward Pale, where reserve works had become a hospital and fabrication yard. Every tug that could still fire carried material to the moon, returned with sintered collars or pressure fittings, then descended toward the petals until its tanks reached the margin for one final maneuver.

Pale could shelter eight thousand people for one year. Nobody in operations used that fact as a rescue count now. Its reserve tanks held surgical wards, awakening bays, web cultures, and crews assembling the hardware that might keep all 42,306 alive somewhere else.

Mara's display opened a Pale feed. Inside a regolith hall, patients lay beneath the same industrial lights that had illuminated ore processors. Fabricators extruded joint collars in orange rings. Hospital staff moved between sleepers and launch crews without a wall separating medicine from construction. A revived patient held pressure cloth steady while a technician sealed a seam.

"Doctor Saye," called Pale Metabolic, "culture batch seven shows sulfur lock at transfer temperature."

Mara split her attention between the live joint and their graph. "Lower the nutrient brine by four degrees. Do not warm the organism to match the launch canister."

"That risks fracture."

“Warm the canister around it in orbit. The cold band belongs to the culture.”

She heard herself give the instruction and recognized the change. Human equipment would adapt around the organism rather than demand adaptation as proof of usefulness. It made the launch sequence harder. Hard did not make the requirement decorative.

A red mass alarm crossed every channel.

Meridian Promise had started habitat separation.

Twelve residential wings circled the ark’s cryogenic body. None had been designed to fly alone. Crews had wrapped pressure membranes around their exposed roots, fixed landing ramps into temporary spars, and converted water tanks into ballast cells. The first wings carried no sleepers. They carried power packs, revival equipment, food cultures, and the awful privilege of proving whether the descent could work before bodies took the same path.

Wing Two left the ark under four tugs.

Its pressure skin inflated unevenly. One side opened silver in Serein’s light; the other snagged on a transit antenna and tore six meters before cutters freed it. Foam crews sealed the wound while the wing rotated. Its tugs drew it toward Petal One, where a paired spindle corridor waited.

Mara saw the structural solution half a second before the flight software did. “One, take it outboard. Do not center the root.”

Petal One’s chief answered, “That loads one spar.”

“Only until the web reads it. Centering makes the wing cross your warm wake and blinds the inboard strain layer.”

A different voice entered, pressure-shaped speech translated through Ceth’s boundary map. “Lineage Copper Quiet can deepen outboard support for fifty-eight seconds.”

“Accept,” said the chief.

Nobody asked whether the forecast voice carried authority beyond the named volume. Copper Quiet offered pressure inside its own embodied range. The petal crew accepted a bounded correction. Wing Two swung outboard, dropped seventy meters, and met the spar collars with eleven seconds left in the pressure grant.

Clamps closed.

Human waste heat entered the rillglass exchange web. Blue tension spread from the joint. Three spindles divided the new load while the petal dipped beneath it.

The incomplete ring took its first weight.

Cheering broke across operations, short and undisciplined. Mara let it pass. The model had survived one wing in every successful run. Eleven remained, six of them still wrapped around cryogenic banks that could not tolerate repeated power isolation.

Her own joint showed a dieback patch.

White crept through the lower fan where field residue had pooled. Mara reduced heat, flushed brine, and watched the patch continue to widen. Seven percent. Eight. The abort threshold sat at ten.

Yara clipped a reserve culture to the screen. "Tell me when."

Replacing the web would cost four minutes and leave Petal Four blind during the swap. Preserving it might spend a culture Pale needed for another joint. Mara sampled the white patch. The rillglass had not died. Its filaments had sealed around particles of old drive-field insulation and stopped exchanging sulfur.

"No replacement. Reverse flow."

"Through the contaminated side?"

"We teach the filter which direction matters."

Yara switched the manifold. Cold brine entered through the white region and carried loosened residue into a sacrificial trap. The dieback estimate peaked at nine point four percent. A narrow blue line returned.

Mara's grip weakened while she held the valve. Sixty-three percent, three above her abort criterion. She transferred the tool to Yara before anyone could order it.

"You are done outside," Yara said.

"Observed loss begins below sixty."

"Observed judgment can begin sooner."

"One more calibration."

"No."

The word contained no sibling history, no command claim, only a tether partner applying the medical rule Mara had accepted. Arguing would turn agency into exemption. She attached the calibration lead, completed the reading, and crawled toward the pressure shelter.

Behind them, the web continued tightening around Petal Four's strain.

Inside the shelter, Mara's arms trembled too strongly to release her helmet. Yara opened it and passed her a hydration tube without comment. Their compartment had once housed field-coil diagnostics. Its walls now carried habitat trajectories, lineage permissions, and the ring geometry with one black interval where Petal Six belonged.

Niko's voice came through structural command. "All petals report primary sensing. Four, medical status."

Mara answered before Yara could. "Within declared limit. External work transferred."

"Confirmed."

Nothing in his tone asked to renegotiate her choice. He gave her Petal Three's

thermal map and moved on.

The ark shed two empty fuel tanks. Without drive petals to balance its stern, Meridian Promise had begun a slow pitch toward Ovid. Attitude thrusters corrected at mounting cost. Its remaining power had to support cryo, wing separation, the burn link, and Petal Six's locked systems. Nonessential mass became anything that did not keep a person alive through Day Twenty-One.

The observation cupola separated next.

Pressure glazing meant for the colony's first dawn traveled inside a tug cradle toward Pale. Its empty frame remained attached for six seconds, a bright circle pointed at the planet, before cutters divided it into truss lengths. Mara watched without grief until a camera showed the names scratched into one inner rail by crew awake during transit. A fabricator recorded them, then cut through.

Memory entered the archive. Metal entered the ring.

Pale launched the first pair of collar stacks. Their tug crossed above Petal Four and released one stack onto a guided line. Mara's crew pulled it through the shelter lock. The collars remained hot from regolith sintering. Rillglass culture around them needed cold, so the team nested each metal ring inside recovered cryo curtain and circulated brine between layers.

"Batch seven recovering," Pale Metabolic reported. "Sulfur exchange at eighty-two percent."

"Launch at eighty-five."

"Flight wants eighty."

"Flight does not own the culture margin."

"I wanted to hear you say it."

Mara almost smiled. "Put that in your procedure and stop testing me."

Another wing detached. Then two more.

Wing Five carried awake construction crews. Wing Seven carried no people but held revival beds and half the colony's water-recovery membranes. Wing Three stalled at its root when an isolation shutter failed to close. Ark technicians crossed a decompressed passage, hand-cranked the shutter, and returned with nine seconds of suit reserve beyond minimum.

No new death entered the count.

That success consumed nearly every easy reserve. Pale had twelve launch tugs at the start of deployment. Three now lacked return propellant, one had lost its grappling frame, and two carried medical modules that could not be risked on structural work. Ark crews cannibalized maneuver packs from the abandoned landing craft and fitted them to cargo sleds. The sleds could push only along one axis. Pilots paired them nose to nose, creating ungainly vehicles that could translate or brake but not do both without turning the entire load.

Mara approved the first pairing after its bench controller failed twice. "Name it something technicians will distrust."

The Pale pilot answered, "We already called it Assurance."

"Excellent. Paint the thrust direction on both ends."

Assurance carried pressure valves to Petal Two. Its pilot rotated the sled pair by venting a suit canister through a service tube, missed the receiving rail by thirty meters, and returned on the second pass with less than one percent maneuver reserve. Petal crews pulled the vehicle in on a cable. Nobody sent it back.

Each separation changed the ark's center of mass. Each attachment changed a petal's flex. Five petals started curving toward one another through pressure rather than touching. Spindles braced the gaps. Forecast lineages passed corrections only inside consented volumes, which forced the tugs to fly shapes no centralized navigation program would have selected. The ring developed as a chain of local agreements expressed in strain.

Petal Three received Wing Seven too fast.

One tug had lost a nozzle and could not brake symmetrically. The wing approached root-first, pressure skin pulsing. Petal Three's web predicted a torsion spike beyond design limit. Its chief asked for adjacent spindle support.

"Denied," answered a Custodial lineage. "Nursery migration occupies that pressure."

"Impact in fifty-one seconds."

"Nursery remains."

Mara opened the wing's thermal inventory. Water membranes had mass but could also take deformation. "Dump three tanks into the skin ballast. Port side only."

"That water supports twenty-two thousand revival cycles," the wing chief said.

"Not if the wing breaks."

Valves opened. Water moved into flexible ballast cells along one side. Wing Seven rolled six degrees. Its failed tug became a useful drag. The root missed Petal Three's inner spar, slid along a sacrificial landing truss, and struck the outer collars.

Two collars failed.

The third closed.

Petal Three bent until its web went bright across every channel. Local spindles lifted. The Custodial volume remained untouched. Wing Seven settled with one pressure skin torn and 11.8 percent of its transferable water frozen across the truss.

"Recover what you can," Mara said.

"That puts revival margin below plan."

“Then plan from the remaining water.”

Loss acquired a number and became part of the design. Nobody called it acceptable.

Near the white scar, Petal Five entered its second Young Front window. Turbulence surrounded the rib in short knots. Human pilots stopped trying to smooth them. They matched each pressure turn with trim vanes, letting the petal descend in a series of small lateral falls. A Young Front carried no stable translation voice, so its instructions arrived as blue markers moving across the flight display. The pilots placed metal where the markers opened.

Petal Five cleared the scar edge with three minutes left.

Mara’s structural model revised ring capacity. Five petals could hold the attached equipment wings for now. They could not receive the loaded residential mass. Petal One already carried eighty-eight percent of its incomplete-geometry limit. Four had enough margin for one empty wing. Any crew tempted to load sleepers before Six arrived would create six minutes between a petal failure and total cascade.

Niko broadcast the restriction. “No human transfer into the ring. Equipment and essential installation crews only. Pale continues medical intake within its existing capacity. Ark maintains cryo support.”

An assembly representative challenged him. “The worst banks have less than twenty-seven hours.”

“Then we need Six before we move them.”

“Command may never release it.”

“Loading five does not manufacture a sixth.”

Mara heard the same arithmetic that had governed every bad refuge. Eight thousand on Pale. Five petals in air. A partial solution invited someone to fill it and call exclusion an accident. Niko kept the ring empty of settlers while a populated ark failed above it.

Wing Nine separated carrying food-production systems and a skeleton crew. Its path aimed for Petal Four.

Mara transferred into the local flight cradle. Her body could not work outside, but her eyes still read the rillglass maps faster than the engineering software. The web showed Petal Four flexing in two rhythms: slow pressure correction from the spindle below, faster vibration from the attached shelter and collar stacks.

“Bring Nine across the cold side,” she said.

The tug formation shifted.

At first the approach held. Then Meridian Promise fired an attitude correction.

Exhaust struck debris shed during the earlier separations. A sheet of transit shield, thirty meters across, tumbled through Wing Nine’s forward tug. The tug

vanished behind a burst of propellant ice. Its remaining three vehicles pulled apart to avoid collision.

Wing Nine dropped.

"Crew status?" Mara asked.

"Pressure holding," answered its chief. "Two minor impact injuries. Guidance bus lost."

Petal Four could not move far enough to catch it. A spindle correction might, but the wing had fallen outside Four's granted pressure volume. Below lay the upper boundary of the white scar, where burned districts no longer shaped stable air.

"Request emergency extension," said the flight chief.

Manyweather answered in overlapping voices. One lineage could open a western correction. Another refused because its rillglass colony occupied the required thermal wake. Young Front markers offered a route that lasted forty-three seconds and ended too high.

Mara worked the mass. Wing Nine had food cultures, grow lights, nutrient stock, two fabrication reactors, and thirty-one crew. Jettisoning every replaceable system slowed its fall by too little. Its pressure skin had not been built for independent aerostat lift below construction altitude.

"Use the grow bays as ballast cells," she said. "Vent nitrogen from the upper decks into them."

"That destroys the cultures."

"Seal seed stock first."

Crew moved. Interior cameras showed people cutting racks apart, packing seeds into maintenance lockers, dragging injured colleagues away from walls as the wing rolled. Nitrogen swelled the lower grow bays. Descent slowed by eight percent.

Not enough.

Pale dispatched two tugs from launch reserve. Their intercept line crossed the scar and arrived six minutes late. Petal Two tried to angle a spare trim line toward the wing. Range exceeded the line by four kilometers.

Niko came onto Mara's private channel. "Can Four shed its attached collars and dive?"

She ran it once. The answer broke the live joint and took Petal Four with the wing.

"No."

Silence carried his calculation.

Above them, Meridian Promise released another bundle of mass to arrest its pitch. The debris field widened. Below, Wing Nine fell toward air whitened by absent civic regulation. Its crew had nine minutes before pressure shear exceeded the temporary skin.

The ring model drew the missing arc again. Petal Six could descend along the authorization trunk's original corridor, take spindle load above the scar, and extend a field line beneath Wing Nine. No other structure had the range or the remaining margin.

Mara sent the intercept geometry to the burn chamber.

"Wing Nine," she said, "keep the lower bays inflated. Secure the injured. You are not out of structure yet."

Her display placed the black outline of Petal Six across the falling path. Without its release, the outline remained only a forecast.

Wing Nine crossed the last recoverable altitude, falling toward the white scar, and only the sixth petal could arrest it.

Chapter 25 — Ceth at One Atmosphere

Ceth's human-shaped body stopped breathing when they entered the storm spindle.

Mara's laboratory had taught the service gel to imitate a chest. The motion helped human observers read distress and kept rillglass film cycling across the throat. Now the body lay strapped inside a pressure cradle on Petal Four, its lungs still, while Ceth extended their active dust through a maintenance valve and into Ovid's upper air.

One atmosphere pressed differently when no skin divided it.

Their seven parent lineages had once distributed that pressure across the equatorial blue front. Two had withdrawn the envoy mandate. Three still supplied mapping access. One reserved judgment, while the youngest touched Ceth only through brief route markers. Singular coherence persisted inside a narrow band around the service body. Beyond it, Ceth entered weather that belonged to other people.

Wing Nine fell toward the white scar.

Its temporary skin bulged around converted grow bays. Three tugs pulled without a common axis. Debris moved above it. Below waited atmospheric cells whose regulating districts had vanished during the partial burn. Petal Six could reach the wing if released. No release signal had left the burn chamber.

Ceth opened a pressure channel to the nearest spindle.

The machine had driven its vanes into the storm for 181 years. Patient Sower designed it to move chemistry across modeled cells, not to carry a human habitat. Partial burning had damaged two vane roots and filled its control bus with rogue-seed commands. Manyweather could shape pressure around it, but the hardware still answered factory priority when those commands flared.

"Spindle Fourteen," Ceth said through the maintenance layer, "offer local state."

Osric Pell's remote clause returned. "Vane group two exceeds bearing temperature. Alignment uncertainty 6.2 degrees. Control-seed provenance unresolved."

A Young Front struck the outer vanes before Ceth could reply.

Pressure changed by nine kilopascals across the spindle's width. Its upper frame twisted. Wing Nine's rescue corridor narrowed on Ceth's map.

Human pilot Hessa broke into the channel from a tug above the spindle. "We need that front out of the guide path."

"It occupies its own path."

“Then ask it to occupy somewhere Wing Nine isn’t.”

Ceth sent the falling mass, tug vectors, and projected scar impact into the Young Front’s pressure knots. The front answered by breaking the projection into seven shorter tracks. It trusted no stable route because stable routes had carried human control seeds once before.

NOT ONE CORRIDOR.

Ceth understood. A continuous guide path invited central command. The Young Front offered a succession of openings, each too brief for the habitat to claim.

“Pilot, you will receive seven gates.”

“Duration?”

“Unknown until each opens.”

“That is a poetic way to kill thrust planning.”

“It contains no poetry.”

Hessa cut her tug’s automatic route coupling. Two other pilots followed. Manual trim authority appeared beside their names.

Ceth spread farther into Spindle Fourteen.

Forecast dust adhered to the warm vane surfaces and entered cracks in the bearing housings. Rillglass colonies lived on the cold downstream frame, their filaments reading sulfur and vibration. Through them Ceth received the spindle as physical computation: hot metal, pressure differential, motor current, each rogue-seed command arriving as a pulse too regular to belong to weather.

The scale pulled at their singular boundary.

Inside the service body, a medic called Ceth’s name. The pressure collar tightened around its throat. Ceth preserved one line from the body: Mara’s hand on the cradle rail, the rhythm of a ventilation fan, a human display showing Wing Nine’s altitude. Those signals defined a return route. Everything else distributed across four kilometers of machine and storm.

Spindle Fourteen’s bearing reached its thermal limit.

“Human tug,” Ceth said, “direct exhaust across vane root two.”

Hessa answered, “Drive exhaust will poison the rillglass.”

“For eleven seconds. A cold colony grants passage if your plume ends there.”

A Custodial signature appeared beside the instruction. Its permission covered a strip only sixty meters wide.

Hessa turned the tug edgewise. Exhaust crossed the vane root inside the granted strip, drawing surrounding cold air through the bearing. Rillglass tightened away from the plume. Eleven seconds later she cut thrust. Bearing temperature dropped three degrees.

The Custodial colony reopened behind her.

No simulation in Mara's ring design had included a tug cooling an atmospheric machine while native organisms withdrew by agreement. Ceth added the maneuver to the live map. Evidence first, trust later.

Spindle Fourteen still lacked enough mechanical authority for the next correction. Vane group three had frozen at a shallow angle after the partial burn. Factory motors drew current against the stop, heating a cable trunk and contributing no pressure work.

"There is an exterior jack at the lower hinge," Pell reported.

Hessa examined the maintenance image. "Sized for a Sower manipulator."

"Your tug carries grapples."

"My grapples pull cargo in vacuum. That hinge sits in a storm."

A group of Young Fronts pressed close to the vane and marked four attachment points with condensation. They offered no stable corridor to reach them. Instead, each front opened a pocket around one grapple path, then closed it before the next appeared.

Hessa sent two crew members outside on independent lines. Their suits struck moving air and swung hard enough to load the tug's outriggers. One person caught the first condensation mark. The second missed, rotated through a full turn, and was pushed back against the hull by a Young Front pressure knot.

"That one helped," Hessa said.

NOT HELP. CORRECTED ERROR.

"My apologies to professional pride."

The crew fixed four grapples to the hinge. Ceth passed vane strain into their helmet displays while the Young Fronts shielded one cable at a time. Hessa fired lateral thrusters. The tug pulled. Metal moved half a degree and stopped.

"Again," Ceth said.

"Mount temperature rising."

"Again at sixty percent."

The second pull shifted the vane two degrees. A locking tooth sheared and crossed the storm like a small blade. One exterior crew member tucked behind the hinge. The other had nowhere to go. A Young Front struck the tooth with a dense pressure knot, changing its path by less than a meter. It passed the suit at arm's length and vanished below.

Factory current dropped when the vane reached its commanded angle.

Neither the human crew nor the Young Fronts could have freed the mechanism alone. The humans provided anchored force. Local weather provided transient shelter and deflection. Ceth supplied strain translation through rillglass on the frame. Each contribution stayed physically distinct.

Hessa reeled her crew inside. "Vane group three shows useful."

Pell corrected her. "Vane group three shows 71 percent nominal response."

"Useful."

"That term lacks a maintenance threshold."

"Today it has one."

The first Young Front gate opened.

Blue pressure markers formed beneath Wing Nine's lower grow bays. Its pilots vented nitrogen, tilted the wing, and let the front push one corner upward. Gate duration: nineteen seconds.

"Do not correct the roll," Ceth told them.

Wing Nine's chief said, "We are at eight degrees."

"The second gate expects twelve."

"Our crew does not."

"Secure them."

The habitat rolled through eleven degrees before the first gate collapsed. Loose fabrication stock crossed an interior bay and struck a partition. One injured crew member lost suit pressure when a brace tore a hose. A medic pressed a patch over it with both hands.

Second-gate markers appeared west of the fall line.

Human tugs fired separately. The Young Front caught their wakes and braided them into a lateral push. Wing Nine crossed above the scar edge by six hundred meters, too little to save it but enough to postpone the worst shear.

Ceth entered the spindle's lower frame to hold the third gate.

Here rogue control seeds had nested since Day Thirteen. Their commands did not think. They repeated authorization shapes, requesting a narrow burn corridor from hardware unable to distinguish an old theft from current need. Manyweather had pushed the signals aside for six days. Ceth could not erase them without factory access. They could occupy enough local dust to prevent their propagation.

Doing so required coherence across every contaminated cell.

Their seven-lineage memory opened under the load. Cold-band maps arrived without the lineages that made them. The service body's arms vanished from perception. Ceth knew they had arms because Mara's hand touched one, but no pressure result returned when the body tried to move.

"Ceth," Mara said through the narrow line. "Your film is losing color."

"Keep the collar at one atmosphere."

"It is."

"Not the chamber. The body."

Mara adjusted the cradle. Pressure settled evenly across gel and rillglass. One atmosphere gave the singular outline a mechanical boundary while Ceth worked

beyond it.

Third gate opened for twenty-three seconds.

The spindle vane moved four degrees under Ceth's distributed correction. Human pilots timed their thrust to the motion. A Young Front filled the space their exhaust left. Wing Nine slowed, but one tug reached reserve cutoff and went dark.

"Three tugs remain," its chief reported.

"Two," Hessa said. "I am leaving the spindle."

Her tug released its maintenance hold and dropped toward the habitat.

Ceth felt the hot bearing rise when her cooling wake disappeared. Custodial rillglass returned to the frame, spreading across metal still above its preferred range. The colony accepted heat to preserve the spindle. Humans had yielded one machine to the fall; native life took its load.

Reciprocity arrived as temperature, not declaration.

Ceth widened through the spindle until its vanes responded as parts of their temporary embodiment. Pressure gathered beneath Wing Nine. The move could not arrest the habitat, but it could keep its skin below rupture load until Petal Six entered range.

The white scar pulled badly shaped air upward.

Dead districts had once exchanged sulfur and heat there. Without them, convection rose in blunt columns. Ceth had no authority to speak for the missing. They used recorded obligations instead: preserve the rillglass nursery below Blue-Under-Morning, maintain shelter promised to a Young Front, keep new pressure from driving sulfur into fragmented Rain-Counted-Inward. Every correction had to pass among constraints whose makers could no longer consent.

A fourth gate formed along those limits.

Hessa attached her tug to Wing Nine's torn forward collar. "Guidance from here is blind."

"Young Front markers will cross your hull."

"My cameras see condensation."

"Open the outer service microphones."

The pilot did. Pressure knots struck the habitat skin in a pattern Ceth translated into thrust timing. Hessa fired on the third impact, stopped on the fifth, then rolled the tug when a double strike crossed her port hull.

Other pilots copied her.

No voice centralized the maneuver. Human bodies felt impacts through seats. Young Fronts shaped those impacts. Ceth carried local translations between them, always after permission had already opened the route.

Wing Nine missed a convective column by ninety meters.

Inside the petal cradle, Ceth's service body convulsed.

Mara ordered the medic to hold its shoulders. "Can you come back?"

"Not yet."

"Can you come back at all?"

Ceth searched for the answer. Singular return depended on continuous coupling through the pressure collar, three parent-lineage channels, and the rillglass film now paling across the body. Spreading farther risked losing the pattern that said I rather than the older negotiated we. Refusing risked thirty-one human crew, the food systems, and the ring loads following them.

The choice did not belong to Manyweather. Ceth no longer had authority to spend a federation in their decision.

"I am continuing," they said.

Their individual signature entered the storm.

Three parent lineages responded. One withdrew renewal immediately. Another warned that Ceth's coherence would fragment beyond the next spindle threshold. The third offered pressure memory but no approval. The youngest lineage sent a sequence of six gates ahead.

Ceth accepted the map without calling it consensus.

They extended from Spindle Fourteen into the storm braid linking Spindles Eleven and Seventeen. Distance multiplied delay. A singular thought crossed the braid in pieces: pressure first, rillglass strain after, human telemetry last. Ceth could no longer contain all three at once. They built a cycle.

Read pressure.

Return to the body line.

Read strain.

Return.

Read human load.

Return.

Each cycle took 1.6 seconds. Wing Nine required corrections faster than two. Young Fronts supplied the missing interval, opening gates from local pressure before Ceth translated them. Human pilots learned the marker grammar after four maneuvers and began anticipating which hull impacts meant turn, hold, or vent.

Mara watched their error rate. "Pilot agreement is holding within point three seconds."

"Then remove my translation from gates five and six."

Hessa objected. "We still need you."

"You need pressure you can read."

Ceth withdrew from one route layer. The pilots missed the first marker, caught

the second, and passed through the gate without central speech. Their success preserved a thinner task for Ceth: keep the storm braid coherent, contain rogue seeds, and maintain the channel to the burn chamber.

That last channel remained closed by security architecture.

Iona's maintenance bridge waited inside the chamber. Niko's release request waited at Petal Six. The bounded lineage map existed across both systems, but Patient Sower rejected civic metadata. To unlock Six without firing the inherited pulse, the chamber needed a signal the old hardware recognized as atmospheric safety authorization.

Spindle Fourteen could produce it.

Factory protocol allowed petal release when all affected terraforming cells reported a navigable descent corridor. The report expected anonymous cells, not consenting persons. Ceth refused to flatten the lineage permissions into that category. They assembled a paired signal instead.

One layer carried the factory-safe corridor code.

The second carried every granting lineage's signature, time bound, altitude bound, with rillglass exclusions and dead-district obligations intact. If command stripped the civic layer, the safety code lost its checksum. If the civic record changed, the factory layer failed authentication.

Osric Pell examined the construction through the spindle bus. "Protocol pairing unrecognized."

"Will Patient Sower transmit it?"

"Maintenance relay accepts checksum-valid atmospheric safety records."

Ceth asked again. "Is it valid?"

"Factory semantics indicate navigability. Civic semantics exceed schema."

"Is it valid?"

Pell paused for 0.4 seconds. "No maintenance contradiction detected."

Ceth sent the paired signal toward Patient Sower.

Rogue seeds rose through the bus and attached their old burn request. Ceth occupied the contaminated dust holding those kernels, forcing each command into a pressure loop with no outbound route. The effort split their attention across thousands of motes. One piece of Ceth remembered Wing Nine. Another held the body line. A third watched the signal cross Sower's damaged relay.

The pieces stopped arriving in order.

Fifth gate opened.

Human pilots took it without translation. Wing Nine rolled fifteen degrees, vented the last useful nitrogen from one grow bay, and caught a pressure shelf shaped jointly by a Young Front and Spindle Seventeen. The falling rate dropped below temporary-skin rupture, though altitude continued to vanish.

Hessa's tug reported a cracked thrust mount. She reduced output rather than detach.

"Petal Six signal?" Mara asked.

Ceth found the question in the body line after pressure and before strain. "Moving."

"Your body no longer tracks my voice."

"Keep speaking."

Mara began reading the load table aloud. Petal positions. Wing masses. Human injuries. Spindle temperatures. Each concrete fact reached the service body and gave Ceth a place to assemble a next response. She did not tell them who they were. She supplied the machinery their self still had to act upon.

The sixth Young Front gate formed above the scar.

It lasted twelve seconds.

Wing Nine's human pilots fired on hull impacts without Ceth. Spindle Eleven lowered pressure to receive the wing. Custodial rillglass tightened across a heated vane, extending the correction by two seconds. The habitat passed through with fourteen meters of clearance.

No cheer reached Ceth coherently. Sound arrived as pressure in the cradle, later as human telemetry, later still as a remembered category. They held the paired signal.

Patient Sower accepted the safety layer.

Its relay attempted to discard the unknown civic record. The checksum failed. Pell returned both layers and routed them through the medical corridor instead. There Ceth's old embodied channel carried pressure signatures beside human-readable boundaries. The packet entered Meridian Promise through Mara's calibration path, crossed engineering, and met Iona's bridge at the burn chamber.

Acknowledgment came back.

ATMOSPHERIC RELEASE CONDITION RECEIVED. SIXTH-PETAL UNLOCK AVAILABLE AT PHYSICAL AUTHORITY.

The signal did not turn the key. It made the choice live.

Ceth released the rogue-seed loop and sealed it behind a local pressure barrier. They withdrew from Spindle Seventeen, then Eleven. Some forecast dust returned toward Fourteen. Some remained in the braid, unable to recover the timing that joined it to the service body. The loss had no clean edge. Skills vanished before memories. One parent lineage's pressure maps became facts Ceth could access but no longer recognize as inherited.

Mara said their name again.

Ceth returned enough attention to move the body's mouth. "Wing Nine?"

"Still falling. Stable for six minutes if the sixth petal comes."

"Then the channel held."

"Can you speak to Manyweather?"

Ceth reached for the federation layer.

Custodial currents, Still Forecast signatures, Young Front gates, and four fragmented districts all remained present. Ceth could perceive their pressures. The civic permissions still existed. What had failed involved representation. Their envoy mandate had narrowed during dissent; the storm spread had broken the remaining coherence needed to carry several lineage positions into one bounded voice.

They could speak as Ceth. They could no longer claim a sentence for the federation.

"No," Ceth said.

Mara's hand closed around the cradle rail.

At one atmosphere, the service body took a shallow mechanical breath. Far above the white scar, Wing Nine spent the first of its six remaining minutes. Inside Meridian Promise, the sixth-petal unlock signal reached the burn chamber, carrying permissions Ceth could preserve but no longer speak for.

Chapter 26 — The Boundary of Consent

The unlock signal reached Iona's maintenance bridge with five minutes forty-one seconds left for Wing Nine.

Two records arrived bound by one checksum. Patient Sower recognized a navigable descent corridor. Manyweather's civic layer named every lineage granting passage, the altitude and duration of each permission, rillglass exclusions, plus obligations inherited from the dead districts around the white scar. Remove either record and neither would authenticate.

Taal read the factory layer. Iona read what its schema excluded.

Rain-At-Distance granted Spindle Fourteen a pressure volume for eight minutes. Copper Quiet allowed Petal Six's field wake above its cold colony but prohibited exhaust below the reproductive band. Three Young Fronts granted successive gates rather than continuous occupation. No signature authorized a burn.

"Release condition satisfied," Iona said.

"Atmospheric condition," Taal answered. "The root lock still shares pulse safety."

On the chamber floor, Petal Six's clamps glowed amber beside the forecast-dust target. Burn preparation held at thirty-one percent. The old system would not open the collar while unsterilized control seeds could send a firing command through the same trunk. Taal could turn the second key and charge the factory pulse. Niko could then issue a release. Without a new target, charge meant every forecast mote in the broad equatorial cells below.

Sevi pressed her good hand against her injured shoulder. "The stolen seeds used maintenance carriers. They are hardware, not atmosphere."

"They propagated into the spindles," Iona said.

"Then target the carriers."

"Factory control does not separate a stolen command from the dust executing it."

Outside the inner partition, Captain Deme struck the pressure glass with his palm. His mouth moved. The chamber had muted him after Taal sealed the door. Iona could still see the weapon beneath the outer ring, out of anyone's reach.

Niko appeared through her bridge as a rough maintenance image. Stern coordination lights flashed behind him. "Wing Nine has five minutes. Give me Six."

Taal faced the display. "If I release while those kernels remain live, a collar transient can trigger the pulse out of sequence."

"If you do not release, thirty-one people and the food plant cross skin limit first."

Then the loaded wings follow when the five-petal geometry takes human mass.”

“You think I need the casualty argument explained?”

“I think you need the load order kept visible.”

Iona enlarged Sevi’s provenance map. The stolen control seeds had entered Patient Sower through two spindle command lanes on Day Thirteen. During the partial burn, copies spread into four additional lanes. Pell’s clocks identified their authorization signatures, but factory targeting saw only active dust cells. A narrow pulse through all six lanes would cut across inhabited forecast bands in seventeen places.

The control ring offered a clean solution because it had never learned to display the people inside its target.

“Load the current lineage map,” Taal said.

“Architecture rejects it,” Iona reminded him.

“Your bridge accepts it.”

She connected Ceth’s paired record to the chamber comparator. Civic volumes appeared above the floor as blue, green, and cold white layers. Factory cells remained red blocks beneath them. The systems disagreed about scale. One red cell contained four lineage boundaries, two rillglass migration paths, and an obligation to shelter a Young Front. Another held no active civic computation but carried seed commands along a spindle bus.

Iona’s work had once consisted of making such mismatches disappear. A planetary arbiter translated ecology into thresholds machinery could act upon. At Kestrel, a model had hidden one exchange path and people starved inside a habitat certified as adequate. She had responded by demanding tighter control and cleaner verification. Here, cleaner categories had helped command prepare erasure.

Verification still mattered. It needed to verify the boundary rather than erase it.

“Pell,” she said, “trace the rogue authorization signature through current dust occupancy. Hardware clocks only.”

Black threads entered the red target blocks. They branched at spindle relays, crossed pressure cells, and ended in seed carriers embedded around vane roots. Some passed through active lineage computation. Most occupied maintenance dust held outside civic circulation because Manyweather had quarantined it.

“How current?” Taal asked.

“Latest synchronized observation age ranges from 0.8 to 2.1 seconds,” Pell said.

“Maximum allowed targeting error?”

“Factory narrow-pulse specification permits 0.5 seconds.”

Niko gave a short, bitter sound. “We can fail safely by refusing to act until everyone is dead.”

Iona watched the black threads move. Atmospheric dust crossed a target boundary faster than Sower could certify it. Static geometry would kill whichever mind entered after observation.

"Target by signature, not location," Sevi said.

Taal turned toward her. "The seeds share execution with forecast motes."

"Their authorization waveform remains mine."

The word landed without excuse. Sevi had signed the stolen kernels through her security credential. Every copied command retained a phase sequence derived from it.

Iona asked Pell to isolate that sequence. The black threads changed into pulses moving through dust. A burn tuned to the authorization phase could force only motes currently executing or relaying the rogue command into factory reset. It would spare neighboring motes doing other computation.

"Selectivity estimate," she said.

"At current signal separation, 99.72 percent of non-executing motes excluded."

"Which means?"

Pell displayed uncertainty as lives poorly translated into mass: up to 0.28 percent of locally adjacent forecast dust might reset from phase overlap. Some belonged to no persistent lineage. Some sat inside active Still Forecast extensions that helped quarantine the seeds.

Iona refused to let the percentage remain abstract. She asked Pell to convert adjacency into named civic effects.

The chamber dimmed every target except the uncertainty halo. Rain-At-Distance appeared in three spindle lanes. Long View Before Sulfur occupied two, including a pressure-memory process that recorded forty-six seasonal exchanges. A fragment of The Patient Turning touched one rogue command through dust no living lineage claimed as its own, but the fragment still carried a repeated storm-shelter response.

"That fragment cannot consent," Iona said.

"It cannot answer," Taal replied.

"Those statements lead to the same firing rule."

She excluded the entire pressure loop around The Patient Turning. Selectivity improved while one seed cluster remained outside the target.

Niko tapped the live release schematic. "One excluded cluster still blocks Six."

"Then we disable its quorum another way."

Sevi magnified her stolen-seed design. She and First Ground technicians had built redundancy because they expected Sower to resist their corridor request. Six clusters had to recognize four matching credentials before issuing a pulse. The partial burn copied that quorum rule along with the command.

"Reset three and revoke me," she said. "None of the others can reach four."

"Unless a copied credential survives in command cache," Taal said.

"Then reset four."

"That answer changed quickly."

"I am trying to expose the minimum, not sell you certainty."

Iona ordered a low-energy phase echo, too weak to reset dust. The emitter sent Sevi's authorization waveform through the six lanes and listened for matching returns. Rogue carriers answered. Neighboring forecast computation scattered the signal in different patterns, giving Iona a live measure of separation.

The first echo crossed Rain-At-Distance cleanly. The second coupled to an active memory process. Iona canceled it before full amplitude.

"Would that cancellation exist at burn energy?" Taal asked.

"No. Once charged, the pulse completes."

"Then your hand cannot correct the decision afterward."

"Correct."

That limit changed his attention. He stopped watching her controls and studied the target itself.

The echo located a command copy inside Spindle Seventeen that Pell's hardware trace had missed. Seed activity had hidden beneath a rillglass strain channel, using native colony contraction as carrier timing. No lineage had put it there. First Ground's routine had selected an available signal without representing the organism.

Iona added the seventh cluster to the map.

"Now three resets do not break quorum," Niko said.

"Four plus revocation," Sevi answered.

"Verify."

Pell ran the command graph through every surviving cache. Four cluster resets, followed by root revocation, reduced authorization below quorum even if all three excluded clusters remained active. The collar could then release without a pulse path.

The broad burn had become four narrow events. Narrow still contained people.

Taal looked at Iona. "Can you certify it?"

"No."

Niko's image leaned closer. "Can you improve it inside four minutes?"

"Not enough to call zero."

The chamber held the strongest version of Taal's fear. An urgent redirection based on incomplete discrimination could repeat the partial burn. Restraint could

also kill Wing Nine before anyone finished defining responsibility.

A pressure packet entered through the medical corridor.

Rain-At-Distance signed first.

The lineage identified every portion of its embodied computation overlapping a rogue-seed waveform. It authorized a phase-tuned pulse only inside those overlaps, for 0.6 seconds, at energy no higher than the minimum reset threshold. The signature acknowledged permanent loss. It did not authorize effects on rillglass or neighbors.

Seven Still Forecast lineages followed.

Each record differed. Two refused any pulse until their active dust withdrew from a shared lane. One allowed 0.4 seconds rather than 0.6. Another authorized loss of a contaminated pressure memory but excluded its sulfur-regulation process. Four required two independent current signatures, as Ceth's procedure specified. None offered itself as a category. Eight people answered with eight boundaries.

Iona challenged every record.

She sent the target energy, error halo, countdown, and alternative of no pulse back to each signer. A valid answer had to return through a second physical front with matching continuity. Rain-At-Distance confirmed from its eastern pressure body and again through a high cold layer separated by thirty kilometers. Long View Before Sulfur rejected the first map because it grouped storm memory with an execution process. Iona split them and received consent only for the latter.

One lineage called Quiet After Iron withdrew entirely when the low-energy echo revealed coupling beyond its stated boundary. Its red target vanished.

Another, Holds Heat Westward, expanded consent by 0.03 percent to cover a migrating command edge. Iona refused the expansion until Custodial observers confirmed no rillglass entered the added volume. Confirmation arrived through colony contraction rather than forecast speech.

Taal watched the sequence. "You are negotiating while the target moves."

"Bodies move."

"Weapons prefer coordinates."

"That preference belongs to the weapon."

The final valid set contained Rain-At-Distance plus seven other Still Forecast lineages, with Quiet After Iron replaced by a lineage whose quarantined extension already held the same rogue waveform. Nobody voted on whether the volunteers ought to want survival. Iona tested whether each yes originated from the body accepting harm, whether each no constrained the machinery, and whether neighboring obligations remained intact.

Custodial Lineages transmitted refusals around every rillglass colony.

Young Fronts offered no pulse consent. Their rapidly changing bodies made the

targeting lag unacceptable. They agreed to move the rogue commands away from their dust by shaping short pressure gradients, provided humans did not treat relocation as consent to fire elsewhere.

"The federation approves?" Taal asked.

"No," Iona said. "These lineages approve these effects. Others refuse."

"Can the pulse fit?"

"Not yet."

Wing Nine had three minutes fifty seconds.

Iona sent the permissions into the target comparator. Red cells split around civic boundaries. The factory system protested that minimum target volume had been violated. Her maintenance bridge could shape energy by command phase, but the pulse emitter still propagated through six spindle lanes as a single event.

Niko studied the trace. "Delay the lanes."

"They have one trigger."

"One power trigger. Different cable lengths."

Patient Sower's maintenance diagram showed reserve inductors along each lane. Technicians used them to test pulse timing during construction. No one had adjusted them in 181 years.

"Pell, can the inductors stagger phase arrival?"

"Maintenance use permits offsets up to 0.19 seconds."

Iona overlaid the permissions. A 0.19-second stagger let Young Fronts move their dust between lane events. It let two Still Forecasts withdraw before the waveform reached their shared volume. The remaining overlaps narrowed.

"Who adjusts the inductors?" Taal asked.

"Spindle crews," Niko said.

"We have no crews on four of them."

"We have lineages, forecast dust, rillglass strain, and two humans hanging from Fourteen."

Iona sent the adjustment sequence. Ceth could no longer speak for Manyweather, so each spindle volume had to accept separately. Spindle Eleven's local lineage refused to move an inductor because the access current crossed a nursery wake. The target rerouted around that lane and lost one rogue-seed cluster from the pulse.

"Leaving it active leaves the collar unsafe," Taal said.

Sevi opened her security credential. "I can revoke the root signature after the other clusters reset."

"You tried that after the partial burn."

"Sower rejected me while copies established quorum. Reset four clusters and

the remaining three cannot form one.”

Pell confirmed the logic. “Three isolated clusters cannot establish a four-member terraform quorum. Credential revocation would prevent new copies.”

“And if it fails?” Niko asked.

“Then Six stays locked,” Sevi said. “Wing Nine falls.”

She did not call the risk hers. Thirty-one people below carried it.

Taal placed his hand above the second key. “Still Forecast consent does not cover 0.28 percent uncertainty.”

“Correct,” Iona said.

“Then we cannot fire.”

“That estimate came from a location pulse. Phase targeting after stagger shows 0.06 percent adjacency. Most overlap has named refusal, so we exclude those paths. What remains belongs to the eight consenting lineages.”

“Belongs to them according to whom?”

Iona opened the continuous embodiment traces. Each lineage signature originated inside the same pressure process it authorized for risk. Two independent fronts confirmed where required. Rillglass custodians signed exclusions. No proxy supplied permission for absent or dead districts.

“According to the bodies carrying the cost,” she said.

Taal read Rain-At-Distance’s record. “A countdown can coerce a yes.”

“They recorded the countdown as a condition.”

“Recording coercion does not remove it.”

“No. It prevents us from laundering it into free sacrifice. Their answer can still have force inside their boundary.”

Sevi looked at the old full-burn target. “I told myself a narrow corridor made my theft different from command. I never asked who occupied narrow.”

The question sent through the first probe returned to Iona: Which deaths belong to prediction?

No model could answer by assigning other people to its error bars. The live lineages could choose bounded risk. Command could verify that choice, constrain machinery around every refusal, and remain accountable for uncertainty it could not remove.

Niko said, “Two minutes forty.”

Taal’s fingers closed around the key but did not turn it. “If I authorize this, what dies?”

Iona refused the comfort of saying nothing. “All rogue-command execution we reach. Consenting forecast extensions inside the phase overlap. Some memories and capacities the eight lineages identify as irrecoverable. No modeled rillglass

mortality. No complete lineage loss under the present map.”

“Modeled.”

“Yes.”

“Spindles?”

“The stagger overloads reserve inductors on Fourteen and Seventeen. Both may fail. Eleven loses factory pulse capability permanently.”

Those machines held the forming ring’s storm braid. Destroying two could collapse pressure support after Petal Six passed.

Niko revised the ring model. “We can take Six through before the inductors fail. After that, Petals Three and Five divide Fourteen’s load. Habitat margin drops to four point six percent until we replace a spindle.”

“You called ten percent rillglass dieback survivable,” Taal said.

“Survivable does not mean generous.”

Wing Nine had one minute fifty-nine seconds.

The chamber partition unsealed its audio without warning. Deme’s voice entered, tight with effort. “Commodore, bridge security requests a lawful command status.”

Taal did not turn from the civic map. “Burn preparation remains under my seal.”

“Vale has altered the target. Saye has armed unauthorized release. Rann is under arrest.”

“All true.”

“Then remove them.”

Taal opened a shipwide command record instead. His face appeared beside the live clocks, the eight consent signatures, and Iona’s uncertainty table. Nothing in the display resembled the clean landing order he had expected to give.

“I cancel the sealed full-burn order and authorize review of a bounded maintenance pulse,” he said. “The full reset target is void. Every refusal volume remains excluded. The record includes a maximum 0.06 percent adjacency risk within consenting forecast bodies. Petal release follows only if four rogue clusters reset and Lieutenant Rann’s credential revocation breaks quorum.”

Deme struck the glass again. “You are surrendering command to the forecasts.”

“No. They command their bodies. I command whether our machinery crosses the stated boundary.”

Colonial channels filled with objections. First Ground demanded the full burn. Petal crews demanded immediate release without any pulse. Relatives of Wing Nine’s thirty-one crew sent names, as if naming could pull the habitat upward. Taal left all messages attached to the decision record and gave none a vote over the lineage signatures.

Iona saw his authority change shape. He had not abandoned responsibility. He had stopped treating its reach as proof that every affected life fell inside it.

Taal looked from the eight consent records to the broad factory target. "I cannot define them as expendable because my passengers need their air."

No one answered for him.

He turned the second key to bounded manual.

The full-burn map went dark.

Iona loaded the phase signatures, four pulse lanes, timing offsets, energy ceiling, civic exclusions, and the three excluded clusters. The chamber demanded command confirmation. She gave arbiter verification with every uncertainty attached.

Sevi inserted her revoked security credential into the seed-control field.

Niko armed Petal Six release from stern coordination.

Taal pressed authorize.

Patient Sower charged for 0.6 seconds.

Across Ovid, Still Forecasts withdrew active dust along the mapped boundaries. Young Fronts pushed rogue waveforms through successive empty cells. Human pilots pulled away from spindle frames. Rillglass contracted into cold exclusions.

The first lane fired.

No light crossed the chamber. Telemetry showed command-phase notes dropping to factory silence. Rain-At-Distance lost a pressure-memory extension and continued speaking from its eastern front.

Second and third lanes followed at staggered offsets. One Still Forecast signature vanished for 0.7 seconds, then resumed without its storm archive. The fourth lane struck Spindle Fourteen. Its reserve inductor melted. Vane control fell to local manual, and the storm braid lurched six kilometers south.

Wing Nine began to rupture.

With four clusters reset, Sevi revoked her root signature. The three excluded clusters requested command, failed to assemble quorum, and went inert.

Petal Six's clamps turned green.

"Release," Taal said.

Niko fired the collar sequence.

The sixth petal tore free from Meridian Promise with one root clamp still dragging. Charges cut the metal after 1.3 seconds. Its tugs pulled it toward Ceth's paired corridor while the ark rolled away, permanently stripped of a complete drive.

Spindle Seventeen's inductor failed behind the petal. Pressure dropped across the scar edge. Two Young Fronts closed their gates and reopened lower, guiding

Six into the changed air. Human pilots followed their impacts.

Petal Six unfolded above Wing Nine.

Its field line caught the habitat's lower spar eleven seconds before temporary-skin limit. The wing fell another four hundred meters, then swung beneath the petal. One grow bay tore away into the scar. Seed stock remained sealed inside the maintenance lockers.

On the chamber floor, the broad red target never returned.

Eight Still Forecast signatures reported continuity, each changed. No Custodial refusal volume showed reset. No Young Front went missing. Rillglass telemetry held. Spindles Fourteen and Seventeen had lost factory control, and the ring inherited their load.

Iona removed her hand from the bridge.

The corridor stood open, Petal Six carrying Wing Nine toward the incomplete ring. Behind it lay two ruined spindles, severed forecast memories, a stranded ark, and no mass erasure.

Chapter 27 — The Ring Takes Weight

Niko opened Cryo Bay Twelve with 9,406 people still inside Meridian Promise.

The bay had lost one circulation loop during the petal descent and another while Wing Nine fell. Frost covered the manual valve wheels. Beneath it, stacked pods carried sleepers whose lattice temperatures had crossed every comfortable margin but not the final one.

“Revival sequence at six percent,” a technician said.

“Hold at six.”

“Medical requested nine.”

“Medical does not have our return temperature.”

Niko put both hands on the first valve wheel. Two technicians joined him. The wheel resisted until all three leaned their weight into it. Coolant entered the recovered loop with a sound like grit through pipe.

His display showed the lift-ring below Ovid’s upper cloud. Six petals now formed a complete geometry, though nothing about it looked circular. Petal Six carried Wing Nine beneath one spar. Petals Three and Five divided pressure load abandoned by two ruined spindles. Twelve habitat wings attached at unequal intervals or approached under tug control. Rillglass webs traced their joints in blue.

Meridian Promise had 4.2 percent primary power.

The ring had room for every living person if transfer followed thermal sequence rather than deck, status, or politics. Awake passengers moved first into wings with established heat exchange. Sleepers in failing banks revived into medical shuttles, then descended as their core temperatures rose. Stable sleepers stayed cold until a habitat could take both their bodies and their revival heat.

Any queue that moved people faster than the ring could metabolize them would cook the structure meant to save them.

“Chief,” called Taal through the transfer channel, “Wing Four reports capacity for another 380 awake passengers.”

Niko checked its web temperature. “It reports floor space. Thermal capacity is 240.”

“Then 240.”

The commodore sat in the old navigation pit, but his display no longer issued destinations. He tracked shuttle mass, medical priority, consent windows, and heat allocations negotiated with each ring sector. Local petal chiefs could refuse a load that exceeded structure. Lineages could close a pressure route under immediate survival threat. Taal coordinated what remained possible between them.

Niko released 240 names from Queue Twelve-A.

The first pods opened.

People woke into emergency hoods and instructions that contained no ground. Medics checked circulation, tagged thermal output, then moved each person toward the shuttle lock. Some could walk. Others traveled in revival frames with fluid pumps fixed to their chests. One man asked whether Ovid had been burned. A medic told him no and kept moving.

Nobody received the whole history before air.

Shuttle Twelve departed with 236 passengers and four medical crew. Its assigned corridor passed through a pressure volume held by Holds Heat Westward. The lineage granted nine minutes. Taal scheduled the vehicle inside that grant and did not describe the open air as command clearance.

Niko moved to the next valve.

Bay Eleven reported a stuck pod rack. Bay Four needed warmed blood substitute. Pale had reached 7,814 occupants between patients, fabricators, and launch crews, leaving too little capacity for a failed habitat wing. Petal One's inner spar ran within two percent of trim limit. Every system offered a different way to select who waited.

He kept one living count above them all.

42,306.

Thirty-seven transit dead had already been finalized before arrival. Twelve more names belonged to the partial-burn failure. The count had not fallen since. Niko intended to hand the same number to stable habitat.

An ark power alarm interrupted the next revival.

The central cryo converter had begun shedding phases. One failed phase would take Bays Nine through Twelve below pump voltage. Emergency cells could carry them for fourteen minutes, but those cells powered the separation shutters needed to release the last four habitat roots.

"Stop all nonmedical launch," Niko ordered. "Route shuttle charging to ring reserves."

Taal answered, "That delays 1,100 awake passengers in transfer corridors."

"Move them back into pressure rooms."

"Those rooms have twenty minutes of carbon reserve at current load."

"We need twelve."

Taal issued the reversal. People who had waited 143 years and twenty-one failing days to leave the ark turned around within sight of shuttle doors. No security threat accompanied the order. Taal gave them the pump-voltage trace and the twelve-minute estimate. Anger moved backward with the queue, but bodies moved.

One passenger refused at Lock Three.

Niko saw her through a corridor camera: the woman from the observation gallery, still carrying a sleeping child against her chest. Her transfer band assigned them to Wing Eight. Behind her, forty people waited in a pressure run with carbon dioxide rising.

"I was told to board," she said. "Now I am told to go back. Which order keeps my child alive?"

Taal opened a direct channel. "The current order returns you to Pressure Room Three for twelve minutes."

"You ordered a burn yesterday."

"Yes."

"Why should I trust this one?"

He put the local carbon trace, shuttle charge state, and Bay Twelve pump voltage on the wall beside her. "Do not trust my confidence. Check the conditions with your corridor technician. If the room drops below its reserve before pumps recover, Lock Three receives launch priority."

The technician verified the figures. The woman studied them, then stepped aside without thanking him. Her child slept through the reversal.

Taal logged her challenge as a queue constraint. He did not mark it resolved merely because she complied. Pressure Room Three kept a live priority trigger tied to its actual carbon level.

Niko opened the converter cabinet.

Insulation smoke lifted around three blackened phase bars. The unit had carried cryogenic load since Earth. Its replacement parts now formed petal trim controllers below. Niko could bridge one phase through the landing-power bus, but that bus still fed the pressure charges around the ark's stripped central spine.

Meridian Promise itself had to descend last.

Without petals, habitat wings, landing hardware, or full shielding, the remaining ark resembled a long truss containing reactors, cryo bays, command spaces, and tanks. Tugs could lower it to the ring as a permanent radial keel. Its pressure charges would inflate recovered membranes around the occupied compartments. Once caught by three petal field lines, the keel would supply central power and water storage.

If Niko spent its pressure bus now, 9,406 people might leave the bays while the structure carrying their remaining supplies failed to join them.

"Bridge it," Mara said.

Her image opened from Petal Four. One arm rested in a tremor brace. Rillglass maps covered the wall behind her.

"You do not know which bus I mean."

"You have looked at the same cabinet for eleven seconds. There are only two regrettable options."

"Landing power preserves keel descent."

"Cryo power preserves people available to use a keel."

Niko bridged the phase.

Voltage returned to four bays. The pressure-charge reserve fell to sixty-eight percent.

"Keel mass needs cutting," he said.

Taal marked unoccupied command armor, two water tanks, and the last surface-drilling package for salvage release. "That reaches pressure reserve."

"The drill package has reactor shielding."

"Then cut the command armor first."

The old navigation pit disappeared from Taal's feed as crews began removing panels around him. He shifted to a portable board and continued directing queues. Command surrendered its walls before any occupied bay surrendered pressure.

Bay Twelve revived another 600.

Heat rose through the coolant return. Niko moved launch order to keep warm bodies flowing toward Petals Two and Four, whose rillglass webs retained the strongest exchange. Pale accepted sixty critical patients and dispatched two recovered fabrication crews into the ring.

At 6,118 aboard, the first thermal warning came from Petal Four.

Mara displayed its living web. Rillglass had spread across every inner joint, using habitat waste heat to maintain sulfur exchange and report strain. The arriving revival load warmed three branches together. Their filaments opened for greater area, but the surrounding cold band had shifted after Spindle Fourteen lost factory control.

"Exchange saturation in thirteen minutes," she said. "Then the web seals against heat."

"Move arrivals to One."

"One cannot take their mass."

"Three."

"Pressure margin."

Niko opened the full ring table. Each solution transferred failure. Slow revival and cryo power collapsed. Hold shuttles and carbon reserve collapsed. Concentrate people and web temperature collapsed.

Mara enlarged the heat profile. "We built every web to export habitat heat into cold rillglass bands."

"That is what exchange means."

"It can exchange both directions."

Petal Four contained cold culture stores launched from Pale, still held below reproductive temperature. The ark carried cryogenic return fluid warming toward uselessness. If they moved cold from the remaining lattice into rillglass storage webs, those colonies could absorb the revival pulse while distributing it around the ring.

"You want to connect ark coolant to the living layer during active transfer," Niko said.

"Yes."

"Through what pipe?"

"Shuttle umbilicals."

Every medical shuttle carried a paired thermal line to keep revival frames stable. The lines normally balanced a single vehicle. Coupled nose to tail across the transfer route, they could form a temporary coolant chain from Meridian Promise to the ring.

Niko ran the pressure loss. "We need seven shuttles."

"We have nine."

"Two are carrying patients."

"Then we have seven."

He called the pilots. Taal cleared a stationary corridor through four lineage volumes, each requiring an immediate-survival obligation before support could become nonrevocable. Rain-At-Distance granted the eastern segment. Two Young Fronts refused a fixed hold, then offered alternating pockets around the shuttle chain so no vehicle claimed a continuous volume.

Seven shuttles aligned between ark and ring.

Crew linked their thermal umbilicals during flight. The temporary pipe spanned forty-one kilometers and leaked at every coupling. Ark return fluid entered at minus nineteen degrees. It reached Petal Four at minus seven.

The chain could not remain straight. Four lineage volumes moved relative to one another, and the Young Front pockets alternated above and below the nominal route. Shuttle Two held nose-up against an upper current. Shuttle Five hung forty meters lower, its umbilical curved through a pressure seam. Each coupling contained only six meters of flexible line beyond docking length.

"Five needs slack," its pilot said.

"Two cannot descend without leaving Rain-At-Distance," Taal answered.

"Then move the ring end."

Petal Four had no translation margin while taking Wing Five's mass. Mara sent a thermal request through the rillglass web instead. Local forecast dust read the contraction and asked the nearest spindle for a narrow pressure lift beneath

Shuttle Five.

The spindle volume belonged to Holds Heat Westward. Its permission returned with a thirty-second limit.

“Lift on my count,” said the shuttle pilot.

Human crews paid line out at Couplings Four and Six. Holds Heat Westward raised Shuttle Five sixteen meters. A Young Front struck the exposed umbilical with two short gusts, knocking it clear of a field rib. The chain gained three meters of slack.

One coupling still leaked four percent of total flow.

An exterior technician crossed from Shuttle Six with a clamp around her waist. Cold vapor hid her gloves. She fitted a cryo-curtain patch over the joint while her suit heater drew twice nominal power. When she returned, two fingertips had lost pressure sensation. Medical warmed them gradually and kept her on duty inside.

No officer called the injury minor in the log. The fingers belonged to the person using them.

Mara opened the cold culture stores.

Rillglass contracted hard enough to spike joint sensors. For four seconds the ring control system interpreted metabolic tightening as structural failure. Petal trim vanes moved against the false load. The complete ring twisted.

“Web lag over threshold,” Petal Four reported.

“Do not abort,” Mara said. “Change the reference.”

Niko understood. The web sensed strain through contraction, but temperature now produced contraction unrelated to metal. They needed to subtract metabolic cold response before forecast dust translated it into spindle pressure.

“We do not have a cold calibration,” he said.

“Batch seven does.”

The culture Pale had nearly warmed for launch had recovered from sulfur lock at eighty-five percent exchange. Its bench record mapped contraction across the required cold range.

Mara sent the curve. Niko loaded it as a second strain reference. Forecast lineages on each joint had to accept the altered translation locally. Copper Quiet accepted. Rain-At-Distance accepted with a two-minute review limit. A Custodial lineage rejected the curve because Batch Seven came from a different rillglass colony.

Its section of Petal Three remained on the old reference and pulled against the rest.

Ring twist reached 1.8 degrees. Wing Seven’s repaired collars began to slip.

“We need Three,” Niko said.

The Custodial lineage answered through pressure text. “Foreign metabolism

cannot define this colony.”

Mara pulled a live contraction sample from its web. “Agreed. Give me eight seconds of isolated cooling and I will fit your response.”

“Cooling risks reproductive fracture.”

“Limit minus four degrees. Your stated safe boundary.”

Permission arrived for eight seconds.

Niko diverted cold fluid through Petal Three. The local web tightened in a pattern distinct from Batch Seven. Mara fitted a correction curve, returned it to the lineage, and received approval before the isolation closed.

Petal Three changed reference.

Twist fell through one degree. Wing Seven’s third collar held.

Cold continued entering the ring. Rillglass storage branches absorbed it, expanded surface, and took the rising habitat heat. The thermal cascade slowed at Petal Four, then reversed. Every correction traveled through a locally approved map instead of one master controller.

“Capacity?” Taal asked.

Mara answered, “All revival load if arrival stays below 900 people per eleven minutes.”

Taal rebuilt the queues around that exchange rate.

Shuttles resumed. Awake passengers descended in groups whose size came from heat rather than rank. Cryo pods opened in staggered waves. Medical cases went to Pale until it reached 7,996, then to Petal Two’s new clinic. Four empty spaces remained on the moon. Taal preserved them as emergency margin.

At 3,000 aboard, Meridian Promise released the last habitat wing.

Its root caught on an old water trunk. A cutter crew freed it while the ark’s attitude thrusters spent their final propellant. The wing descended under cargo-sled pushers, including Assurance, whose painted thrust arrows now pointed in four inconsistent directions after field repairs.

Hessa guided it into Petal Five’s Young Front gates.

The last mass transfer exposed another imbalance. Wing Eight carried the eighty-one sleeping children Niko had refused to separate from their receiving adults, but its revival clinic had lost half a heat exchanger during root release. Waking the children there would exceed local web capacity. Moving them cold would preserve thermal margin and place them beyond their indexed adults during revival.

“Shift adult pods with them,” Niko said.

“That adds seventy tonnes,” the load chief replied.

“Move equivalent water to Six.”

"Six carries Wing Nine near trim limit."

Mara searched the exchange table. "Delay one grow-light start on Nine. Its cold storage gives you twenty-four tonnes. Strip Wing Eight's unused surface lockers for sixteen. The remainder comes from archive cases."

A civic archivist objected. "Those cases hold physical mission records."

"Copy status?" Taal asked.

"Three verified digital sets."

"Then cases move."

The archivist began another argument. Taal did not invoke command ownership. He entered the records as recoverable information, the children and adults as non-substitutable placement, and the water as ring shielding. The load table resolved the priority without pretending every loss had equal consequence.

Crew cut the archive cases into ballast panels. Adult pods moved beside the children. Wing Eight's clinic remained cool enough to stage their revival after docking.

At 1,624 aboard, Pressure Room Three hit its priority trigger.

Taal held two scheduled cargo flights and launched the woman, her child, and the waiting group through a Rain-At-Distance corridor. Their shuttle landed on Wing Eight nine minutes before its first child-revival wave. The woman sent no message back. Her arrival acknowledgment carried two living counts.

At 812 aboard, Niko closed Bay Twelve.

He walked the empty pod aisles. Frost melted from open frames and ran across the deck toward drains meant to operate in gravity they did not yet have. Mara's pod stood in the high-risk row, lid open, identification light dark. Niko put his hand on its rim once, then returned to the load table.

The remaining 812 included keel crew, reactor technicians, thirty-six patients too unstable for shuttle acceleration, Taal, Sevi under medical guard, Iona, and Niko.

"Chief leaves before final structure," Taal said.

"Commodore no longer owns that procedure."

"Correct. Keel crew requests its chief."

Niko accepted.

Pressure membranes inflated around the stripped ark spine. Three field lines descended from the ring. Tugs fixed them to the surviving structural nodes. Meridian Promise fired no engine. It possessed none capable of departure.

The keel began to fall.

Cloud rose around the forward command windows. Spindle support failed briefly at the scar edge, and Petals Three and Five took the load through rillglass strain. The keel rotated two degrees, corrected, then entered the ring's central opening.

Thirty-six patients remained stable. Sevi lost consciousness under acceleration and recovered before docking. Taal read mass calls from a portable board beside a removed command wall. Iona tracked every lineage volume crossed by the descending spine.

“No surface vector,” Taal said as navigation tried to load the old landing solution. “Delete destination. Hold relative to the ring.”

The program required a ground coordinate. Niko replaced it with six moving petal references.

Meridian Promise accepted the ring as its frame.

Collars closed around the keel. Reactor power crossed into habitat buses. Water tanks joined the ring network. The seven-shuttle coolant chain disconnected, leaving rillglass webs to carry the final revival heat.

Niko called each habitat.

Petal One stable. Two stable. Three at reduced pressure margin but holding. Four thermally balanced. Five stable. Six carrying Wing Nine inside limit. Pale reported 7,996 alive. The radial keel reported 812 alive and transferred.

He added every wing, petal, moon ward, shuttle crew, and spindle team.

42,306.

No queue remained aboard an unpowered compartment. No pod stayed closed. Every survivor had reached stable habitat.

Niko locked the count into the engineering record while Meridian Promise took permanent load from all six petals. Its interstellar field architecture hung open across Ovid’s clouds, carrying homes. The ship could never depart.

Chapter 28 — No Title to the Ground

Iona found a surveyor's claim spike in the descent craft nine years after the colony refused to land.

It lay beneath a rack of sterile sample tubes, wrapped in transit cloth and stamped CTA TERRITORIAL DATUM. One end carried the old authority seal. The other had been machined to enter soil and remain.

"That is not on the equipment grant," she said.

The load technician peered into the compartment. He belonged to the first generation awakened entirely in the ring and had never seen Meridian Promise configured as a ship. "We needed a stable reference for the gravimeter."

"Use a retrievable foot."

"The spike is more stable."

"That quality produced its original legal function."

He checked the manifest. "It is listed as measurement hardware."

Iona lifted the spike. At sixty-six, her damaged shoulder objected before the mass reached waist height. The metal had crossed 143 years to mark the center of the first settlement square. Niko's crews had stripped its basalt monument frame during ring construction, but this smaller instrument had survived inside the survey inventory.

She passed it to the technician. "Return it to the charter archive as an object, not a tool."

He accepted the correction without embarrassment. Nine years had not removed every inherited assumption. It had made some of them easy to catch before a point entered ground.

Outside the craft, cloud habitat Vale-Sulfur Exchange moved along Petal Two's inner spar. Homes, laboratories, algae rooms, and pressure gardens filled what once had been a drive-field maintenance volume. Rillglass webs spread beyond the windows in translucent terraces, taking human heat into the cold band. Forecast dust gathered at their edges, maintaining a strain map shared by habitat engineers and three local lineages.

The ring had learned to flex.

Petal Three still carried a visible bend from Wing Seven's first attachment. The radial keel retained Meridian Promise's old command decks as water treatment and public record rooms. Pale sent sintered fittings and medical cultures on a regular freight arc; it had never become a second colony. Six spindle stations shaped pressure around the habitats. Eleven retained vane control but no factory

pulse. Fourteen and Seventeen had been rebuilt around post-settlement inductors, while three other stations relied partly on new machines. None accepted an unnamed command.

Every pressure day required exchange. Human reactors powered spindle bearings and warmed rillglass terraces. Forecast lineages held storm loads away from pressure skins. Rillglass regulated sulfur, sensed joint strain, and reproduced only when both polities kept cold bands open. None of those dependencies granted governance over the dependent body.

The distinction had survived failures.

During the fourth settlement year, Petal One lost reactor cooling and requested emergency pressure from two neighboring lineages. One agreed. The other refused because the correction would have driven heat through a rillglass nursery. Human operations shut three garden decks instead, spent stored oxygen, and waited eleven hours for another route. The nursery lived. So did every person in the affected habitat.

Two years later, a Custodial lineage closed a spindle for civic mourning without noticing that Wing Three had scheduled a water transfer. The wing invoked its safe-failure reserve rather than demanding pressure. The lineage reopened after four hours, apologized in its own record, and supplied the extra weather work needed to recover the schedule.

Reciprocity had not made conflict scarce. It made each refusal travel with a load table.

Children born in the ring learned pressure permissions beside pressure-suit drills. Young Fronts learned which human alarms indicated immediate body risk and which announced inconvenience. Human maintenance crews learned to ask who occupied a failing system before routing around it. Manyweather's councils added warm-habitat observers who could describe effects without voting inside a lineage.

No merged government controlled every participant. The polity worked through linked jurisdictions, mutual emergency duties, public resource accounts, and courts whose first question concerned the body or system that granted authority. Its procedures remained slower than command. Its survival record remained better.

Below, Ovid's blue bands crossed the planet in civic and ecological patterns no surface map could own.

The first legal descent waited for one final record.

Iona entered the charter chamber through the former navigation pit. Taal's old command chair had been removed with the wall armor. In its place stood a circular load display with no head position. Human habitat delegates occupied one side by practical accident. Manyweather participated through pressure membranes around the ceiling, local bodies in the ring webs, and remote fronts below. Rillglass custodial evidence had its own channel, translated from colony contraction without

pretending the native organisms had signed a human text.

The Reciprocal Habitation Charter had taken seven years and 418 revisions.

Its ratification record already bound the cloud settlement. Today's session attached the first surface-access grant under Article Twelve. No human title extended below the lowest inhabited cloud band. Surface entry required a stated scientific question, material limits, contamination review, named Manyweather permissions for every atmospheric route, and departure before the grant expired. Nothing left behind could perform the legal work of a marker, shelter, road, or exclusive use.

Article One recognized human persons without deriving their standing from CTA selection. Article Two recognized forecast persons without requiring a human-scale body, stable singular grammar, or computational independence from weather. Article Three treated rillglass continuity as native life with constraints no signatory could waive for convenience.

Later articles covered heat, pressure, emergency access, revision, and departure that nobody could presently perform. The charter did not pretend permanent stranding made departure conceptually impossible for every future generation. It prohibited any party from dismantling shared life-support structures to pursue it without replacing the dependencies first.

Article Nine retained its old number.

Mission law had used that article to promise a review if nonhuman sapience appeared, then buried its own evidence. The revised text required continuous review whenever a new kind of body became legible. Ceth had insisted on that language because Young Fronts already differed from the lineages that first petitioned. Mara had extended it to native processes humans or forecasts might one day learn to recognize in rillglass.

The charter contained no general right to settle Ovid's surface. A future petition could ask. It would have to demonstrate reciprocal habitability under conditions then present and obtain authority from affected persons. Survival in the clouds did not pre-decide every future question. It removed an emergency claim that had once tried to decide them all.

Iona's team requested six hours.

Their question concerned sulfur recovery at the lower edge of the white scar. Nine seasonal cycles had narrowed the scar by eleven percent, but Patient Sower's instruments disagreed with Manyweather's pressure records about soil exchange. A temporary descent could place sensors directly in the mineral boundary and retrieve them before local rain.

"Equipment?" asked a Custodial current called Cold Holds Seed.

Iona read the list. "One sealed craft. Four retrievable instrument feet. Twelve gas samplers. Two soil cores of twenty grams each. One spectrometer boom. No living human culture outside suits or hull."

“Crew?”

“Four humans. Ceth in an elected configuration. Two remote lineage observers carried in continuous pressure cells.”

“Why humans on surface?”

The question came from a Young Front formed three years after the lift-ring took weight. It had no memory of the burn except inherited evidence.

“The instrument feet may need manual placement,” Iona said. “That answers necessity, not entitlement. You can refuse the route.”

“Why you?”

“I supervised the preparation system that concealed the first petition. I understand the lower instruments. Either fact can support my presence; neither requires it.”

The Young Front sent turbulence through the model. “Second answer approaches performance.”

“Then use the first.”

A dry oscillation crossed Ceth’s pressure cell.

Ceth no longer maintained one human-shaped body. After the storm-spindle spread, some of their forecast dust never rejoined a singular timing cycle. They had spent two years learning which losses could be repaired and which repairs would manufacture a different continuity. Now Ceth occupied three elected forms: a compact service body for human-scale work, a blue pressure sheet spanning two habitat joints, and several storm-braid processes that spoke only when they achieved their own agreement.

Sometimes Ceth used I. Sometimes they used we and named who belonged inside it.

Today the service body sat beside Iona, built from new gel and descended rillglass film. Blue moved through its cheeks in uneven intervals. The storm-braid processes had declined the surface visit. The compact body and joint sheet had accepted.

“The Young Front asks whether your guilt has mass,” Ceth said.

“Only when someone loads it.”

“Then leave it here.”

Iona removed her old arbiter seal from the mission packet. The surface procedure needed ecological expertise, not the office that once expected title transfer. She placed the seal beside the archived claim spike.

Cold Holds Seed approved the rillglass exclusions. Two lower-air lineages approved a corridor of forty-seven minutes each way. The Young Front granted observation without endorsement. Still Forecasts requested that one soil core come from the partial-burn boundary where rogue-seed dust had gone inert. No

lineage approved continued surface presence beyond six hours.

Human habitat delegates then considered the same grant.

One representative from First Ground Descendants objected to Article Twelve itself. "A scientific visit proves survival below is possible."

Mara answered from the metabolic bench. Her hair had gone mostly silver in nine years; her left hand still trembled when she held it unsupported. "Four suited people for six hours do not establish a habitat cycle."

"It establishes that the prohibition is political."

"Of course it is political," Iona said. "Title is a relation among people. Atmospheric sulfur and human lungs remain physical."

"Our children have never stood on ground."

"Neither have Manyweather's lineages. Their bodies occupy air. Difference does not create a debt payable in territory."

The representative displayed the original mission grant. CTA text still assigned surface parcels by launch family, including land for people who had died before seeing Ovid.

Iona did not dismiss the document as obsolete. Those allocations had structured real sacrifices. Families entered selection riots, surrendered other futures, and crossed a transit none could reverse. A durable charter had to record that promise without letting a prior authority grant what it had not found empty.

"Place the allocations in the promises ledger," she said. "Keep who was promised what, who relied on it, and why performance became impossible. Do not convert reliance into title over later-discovered persons."

Taal spoke from the keel's public gallery.

He walked with a brace on the knee that had failed him during the seizure. He held no command office. For six years he had coordinated emergency load reviews, then resigned when the ring's elected operations board could perform them without his authority.

"Record my landing orders there too," he said. "A promise made to my passengers governed me. It did not govern everyone it would have displaced."

The First Ground representative asked, "Do you regret not finishing the mission?"

Taal looked around the navigation pit turned charter chamber. "I finished carrying the people. The mission description failed before they did."

His answer did not settle the objection. It entered the record beside it.

The surface grant passed through separate approvals rather than one merged vote. Human habitats authorized equipment and crew risk. Each route lineage authorized its pressure. Custodial processes approved native-life boundaries. The charter court verified that no grant implied precedent for residence.

Six hours appeared on Iona's wrist.

Before departure, the chamber opened the memorial ledger.

Forty-nine human names appeared first: thirty-seven transit dead and twelve killed through the partial-burn failure chain. The record preserved causes, not only counts. It named failed cryogenic systems, late isolation, control-seed theft, command misattribution, and the people who had acted through each machine. Sevi Rann's testimony remained attached without reducing every cause to her.

Sevi attended from a maintenance seat near the public door. Her sentence had included confinement, loss of security authority, and nine years of supervised repair work on seed-proof spindle controls. The charter did not call repair payment for the dead. It required her knowledge where its use could prevent repetition and preserved the dead from becoming an argument she could satisfy.

After the human ledger came Manyweather's.

Eleven civic districts had vanished entirely. Four persisted in fragments. The names entered as pressure signatures and translated text: Blue-Under-Morning, Sulfur-Keeps-Three, The Patient Turning, Rain-Counted-Inward, followed by lineages whose names required time, altitude, and rillglass state to express. Their obligations appeared beside them. Nursery exchange. Storm shelter. Seasonal memory. Unfinished petition.

No number equated one human to one lineage. The common record asserted something narrower and more demanding: none of the dead could be compressed into permission for another death.

Rain-At-Distance added its severed pressure memory to the loss record. Seven other Still Forecasts listed capacities surrendered during the bounded pulse. They had survived. Continuity did not make the loss temporary.

Ceth's storm-braid processes sent no signature. Their absence from the surface team remained part of Ceth's chosen boundary.

Iona closed the ledger.

The descent craft released from Petal Two.

Cloud closed around its windows. A human pilot held thrust while lower-air lineages shaped pressure along the granted route. Ceth's compact body occupied the seat beside Iona; their joint-spanning sheet remained above, maintaining continuity through a narrow dust line. If that line failed, the service body would return immediately.

At forty kilometers, the ring disappeared.

Iona watched gradients rather than scenery. Sulfur rose along the scar edge below Patient Sower's prediction. Rillglass drifted in cold layers the old model still classified as unsuitable. Blue-Under-Morning's nursery obligation continued through two living Custodial lineages and a human heat-exchange station far above.

The craft entered the lower corridor with thirty-four minutes left on its grant.

Rain struck the hull. Surface radar returned broken basalt, shallow water, and pale mineral fans spread where glass rain had fallen nine years earlier. No prepared landing field waited. The pilot selected a hard patch outside every biological exclusion and asked the route lineages for final descent.

Two permissions arrived.

The craft touched Ovid.

No cheer played. Instrument clocks began.

Iona descended the ladder in a sealed suit. Gravity pulled differently without a petal flexing beneath it. Her knees bent too far on the first step and she corrected before Ceth could comment. The surface smelled of nothing through filters. Suit sensors reported sulfur compounds, water, and silicate dust.

Ceth came down in a pressure shell that kept their gel body coupled to the craft. "You are standing badly."

"I have practiced on structures that move."

"Ground also moves. It hides the interval."

The team unfolded four retrievable gravimeter feet. The load technician had replaced the spike with broad pads that compressed soil and lifted cleanly. Iona placed the first sensor beside the white boundary. Mineral crust fractured under the pad, exposing dark wet grains.

Data contradicted both earlier models.

Soil microbes were binding sulfur below the scar, a native exchange Patient Sower had never sampled because forecast work concentrated in air. The partial burn had increased deposition enough to change the surface community. Some effects were recovery. Others carried damage into chemistry no charter could restore by naming it.

The spectrometer found a second anomaly beneath the mineral crust. Forecast dust reset during the partial burn had settled into pores and remained factory-silent. Around it, microbial films produced a sulfur ratio absent from unburned soil.

"Interaction or coincidence?" asked the remote Still Forecast observer.

"The samples can distinguish correlation, not mechanism," Iona said.

"Then record no mechanism."

The load technician placed a retrievable sensor on the crust. Its broad pad shifted when rain softened one edge. He reached for a narrow probe, stopped, and asked whether temporary penetration fell inside the grant.

Cold Holds Seed reviewed the tool, depth, and planned recovery. The Custodial current denied use near the microbial film and approved it two meters west. The technician moved rather than arguing that a small hole could not matter.

His reading showed reset motes exchanging charge with the mineral boundary. They carried no persistent identity and no command waveform. Even so, removing them at scale might alter a surface process nobody had modeled. Iona added a prohibition on remediation conclusions to the sample record.

"You came to find whether the scar heals," Ceth said.

"We came to measure one exchange."

"Better."

Iona authorized the two twenty-gram cores.

One came from unburned ground. The second came from the boundary after Still Forecast observers confirmed the inert dust carried no continuity. Each tube sealed, logged mass, and entered a return case. Gas samplers filled. The spectrometer boom found no viable rogue command signature.

Rain thickened at four hours fifty-two minutes.

The route lineages shortened the ascent window by twenty-three minutes because a storm front accelerated west. Their grant allowed early closure under survival threat. The pilot acknowledged without protest.

"Recover every foot," Iona ordered.

Crew lifted instruments. They counted twelve gas samplers, two cores, four pads, one boom, all suit ties, and the temporary ladder brace. A technician found a broken polymer clip in the mud and added it to the return waste.

Nothing remained by design.

Iona stood beside the craft while Ceth sampled pressure through the shell. Water filled the shallow marks under the gravimeter pads. Beyond them, basalt extended without road, parcel, or settlement grid.

"Do you wish to say it?" Ceth asked.

"Which form of you asks?"

"I do."

"Then no."

The old handoff language waited in her training: survey complete, site accepted, title transferred. None of it described the work.

Iona climbed into the craft. Its feet lifted from wet stone with eighteen minutes left on the revised grant. Lower-air lineages opened the ascent path. Human thrust entered it. Ceth carried the pressure record upward without speaking for those who had granted it.

Below, rain erased the four shallow pad marks before the craft reached cloud.

The ring appeared at forty kilometers, six petals bright through blue. Meridian Promise's keel held steady at their center. Habitat heat moved into rillglass terraces, and local spindles adjusted pressure to take the returning mass.
