Act 1

Chapter 01 — The Tug at Nacre

Kessa felt Nacre-9 move through her gloves.

The sensation came up the grapple line while she hung three kilometres from the service spindle, boots locked beneath Threadbare's forward work rail. One tug meant Sena had adjusted their drift. Two meant a grapple tooth had slipped. This came as three measured pulls, each too soft to trip the line alarm and too deliberate to blame on cooling metal.

She froze with the cold-shear cutter braced against the freight collar. Beyond her visor, the abandoned ring turned in patient silence. Its near side had already been opened into bright ribs. Farther out, Nacre's star burned in duplicate arcs around the anchor's dark center. Nine resonator stations held their old positions in a wheel too large to take in without head movement.

A second three-beat load reached her palms.

"Sena."

"I felt it." Her pilot's voice arrived without static. "No thrust here. Station reports green geometry."

"Station always reports green until somebody invoices red."

Kessa eased the cutter away from the collar. Vapor from the unfinished cut glittered, curved toward the lens center, then resumed its outward spread. The freight ring carried no power. Its registry had expired nineteen years earlier. Nothing attached to it could have pulled twice with the same patient rhythm.

Inside the tug, a warning chimed.

Sena did not read it aloud. "We moved seventeen metres."

Kessa checked the stars instead of her wrist display. The paired arc of Elistor had widened by less than the thickness of a hair. "Toward the spindle?"

"Across it. The cage says we didn't move at all."

That answer chilled her more efficiently than the suit loop. A tug could lie because a thruster valve stuck, a gyro drifted, or a pilot hoped the chief routebreaker would discover the problem without making it public. A resonator cage could lie only in concert. Nine stations measured each other continuously. Their agreement defined the route more surely than any ship's instruments.

Kessa unclipped the cutter and secured it against her thigh. "Bring us in one metre per second. No auto-correction."

"Kess, the collar contract pays by recovered mass."

"So recover me first."

“Already had that in mind.”

The work rail shivered beneath Kessa's boots. Threadbare reeled the grapple drums while Sena applied manual thrust. The freight collar turned away from them, or seemed to. In bent space, motion often offered several equally convincing stories. Routebreakers survived by choosing the story that left their fingers attached.

A discarded beam drifted between tug and spindle, spinning end over end. Kessa had marked it twenty minutes earlier as harmless. Now its path crossed her retreat line.

“Hold us.”

Thrusters stopped. The beam continued inward.

Kessa watched its jagged end approach the grapple line. Half a metre of collision would suffice. The line carried enough stored force to tear the work rail from Threadbare and take her with it. She reached for the explosive release, hating the loss before it happened.

Darkness beneath the beam altered shape.

No surface appeared. Starlight merely bent around a broad absence at the anchor's center, like cloth lifting over the back of something submerged. The beam's spin slowed. Its forward end slewed aside without contact or visible exhaust. Metal passed the grapple line by nine metres and continued toward Resonator Four.

Sena breathed once over comms. “Tell me you did that.”

“My professional reputation depends on lying better.”

Nacre control cut into their channel. “Salvage tug Threadbare, cease operations. Telemetry indicates an uncontrolled recoil from target mass.”

Kessa looked at the freight collar. It still turned on the same axis. “Your telemetry has ambition.”

“Confirm cutter secure and prepare for retrieval.”

“Confirm cage status.”

“Green.”

“Raw station timing, please.”

A pause opened. Not long enough to claim transmission delay, but long enough for a person to see which answer had been authorized. “Cage status remains green. Your target experienced material recoil during cutting.”

“The target moved away from the cut.”

“Routebreaker Rho, prepare for retrieval.”

Use of her name meant a supervisor had entered the exchange. Nacre-9 employed decent controllers and frightened managers. Kessa had outlasted both kinds at six anchors. She knew the pressure points: berth penalties, contamination

clauses, labor stops, and the phrase personal safety concern spoken in exactly the right register.

She released one boot and pushed along the rail toward the grapple fairlead. "I am inspecting possible line damage before retrieval."

"You are instructed to return inside."

"Then log a direct order to cross a loaded line without inspection."

No order entered the work slate.

Sena made a pleased sound. "How long?"

"Four minutes before someone remembers they can revoke our berth."

"Three, if that supervisor has met you."

Kessa moved hand over hand. Frost filmed the fairlead where the grapple cable entered its drum housing. No broken strands showed. A shallow indentation crossed the outer guide, fresh enough that powdered ceramic still drifted from it.

She put two fingers against the mark.

Three pulls answered.

This close, the rhythm contained a smaller motion inside each beat. Pressure rose, trembled, and released. Not a signal sent along the cable. The guide itself changed load as the geometry around it flexed.

Kessa switched her suit camera to macro and followed the indentation. It continued past the fairlead onto the work rail, a hairline seam curving against the manufactured grain. Threadbare had accumulated many repairs across forty-six years, some lawful and most functional. She knew every exterior patch because she had either made it or complained about the person who had.

No one had cut this seam.

Something translucent filled it. Under the suit lamp, the material resembled drawn glass with a faint green cast. It had entered through a bolt hole, crossed the rail beneath two layers of insulation, and closed around the fairlead bracket in branching threads.

"Kess?" Sena asked.

"Kill my lamp."

Darkness closed over her hands. Nacre's doubled stars gave little useful light. The branching material remained visible, not by shining but by bending pinpricks into minute hooks. Each hook shifted with the distant pulse.

Kessa touched her sample blade to the thickest branch.

The rail kicked.

Her left boot tore free. The grapple line snapped taut, throwing her shoulder into the housing. Pain flashed across the old scar in her palm. She locked one elbow through a rail loop before the next motion could take her.

"Kessa!"

"Still attached."

"Your heart disagrees."

Nacre control spoke over Sena. "Immediate retrieval. This is a direct safety order."

Kessa could hear the satisfaction of someone who had finally found the proper phrase. She also heard fear beneath it. Their station instruments had seen the kick.

"Log the worker stop," she said.

Silence followed.

"Routebreaker Rho, specify cause."

"Unclassified live load in Anchor Nacre-9's salvage perimeter. Potential cage coupling. All powered cutting stops pending inspection."

The formal words tasted older than any of them. Routekeepers had won the stop after four crews died dismantling a corridor whose operators kept calling it closed. No supervisor could cancel one without placing a named engineer outside, in person, with equivalent exposure.

Kessa cut the translucent branch.

The sample blade met almost no resistance. A five-centimetre filament came free and curled toward her glove. Its severed end closed as she watched, turning from ragged to smooth. The material left in the seam withdrew beneath the insulation.

She trapped the filament in a magnetic specimen tube. It did not adhere to the tube. It hung in the center, bending the rail behind it into a pale crescent.

"You have ninety seconds," Sena said. "A security skiff just undocked."

"Bring the forward lock to me."

"That would require moving the tug."

"Good. Let's learn whether we own that motion."

Sena fired the manual jets. Threadbare shifted with a clean acceleration Kessa felt through the rail. Behind it came another motion, broad and slow, from the anchor's center. The tug's star tracker painted two paths at once. One belonged to the ship. The second belonged to the space through which it flew.

The security skiff crossed from Resonator Two, blue strobes useless against the dark. Kessa pulled herself into the lock as it approached. She sealed the outer door, clipped the specimen tube inside her suit pouch, and waited through a pressure cycle that seemed designed to waste the remainder of her life.

Sena met her at the inner hatch with both hands planted on the frame. She wore her black hair shaved close for helmet seals and a pilot's restraint harness over a faded undershirt. "Please tell me you stopped for something better than a scratch."

Kessa withdrew the tube.

The filament curved toward Sena's chest.

Neither woman moved.

Through two bulkheads, Threadbare's grapple drums knocked three times.

Sena leaned away from the specimen. "Does Anu know how to identify haunted glass?"

"Anu identifies things that embarrass people with larger budgets."

"Close enough."

Kessa crossed the narrow repair gallery toward the cockpit. Crew emerged from the drum passage as she went, fastening collars and checking wall displays. Nineteen people could make an eighty-three-metre tug feel crowded when the stars changed shape. They looked to her because routebreakers owned exterior hazards even when nobody owned the hazard itself.

"Cold tools only," she told them. "No automatic grapples. Jori, isolate both drums from cage timing. Pell, pull local instrument buffers before station overwrites them."

A rigger named Vasken glanced toward the lock. "Control says target recoil."

"Control says what fits in its report."

"What do you say?"

Kessa considered the specimen against her ribs. "I say we don't know what moved."

That answer unsettled them more than a confident lie. Good workers understood the danger of a chief who named a problem too early.

The cockpit wrapped around two acceleration couches and a manual console Sena had preserved through three refits. Nacre's lens center filled the forward cupola. Under ordinary operation, the hollow could not be seen. The cage defined it through absences: a ring of lensed stars, a corridor mouth blacker than the surrounding dark, calibration sparks returning from impossible angles.

Today the absence had posture.

Kessa strapped in beside Sena. "Show ship track independent of cage references."

"Using what?"

"Freight collar spin, skiff drive plume, Nacre proper motion."

Sena built the solution by hand. Three pale vectors crawled across the cupola. They disagreed by sixteen metres, then eighteen.

The security skiff called them. "Threadbare, cut propulsion and accept boarding. Your worker stop has been received. Station authority requires surrender of all samples and local recordings under corridor safety law."

Pell spoke from the repair gallery. "Buffers copied. Station requested checksum sync twice during the pull."

"Did it get one?" Kessa asked.

"I was raised better."

Sena muted the outgoing channel. "We can run. Not far, not before they lock the berth credit, but running has aesthetic value."

Kessa turned Tomis's torque key between two fingers. It hung from the console where she had left it after the last compressor service, brass edges rounded by two generations of Rho hands. Tomis had carried it at Lark-3. The Charter returned it with his suit seals and a finding that blamed him for failing to compensate an anchor fluctuation.

She had signed receipt. She had not appealed.

A fresh vibration touched the console.

Three beats.

The filament in her pouch tightened against the fabric. On the display, every station continued to report nominal geometry. Resonator outputs matched to six decimals. Power draw stayed flat. Such agreement no longer reassured her. It suggested editing.

"Open a channel to Anu Sel," Kessa said.

Sena's hand hovered. "Station ecology?"

"Gravitational ecology."

"I thought the Charter dissolved that program."

"They dissolved the funding. Anu kept the instruments."

The call failed before routing. A red notice replaced it: EXTERNAL COMMUNICATION SUSPENDED DURING SAFETY REVIEW.

Security repeated its boarding demand.

Kessa studied the station wheel. Resonator Four sat beyond the discarded beam, which continued its altered drift. Control had not corrected the object or acknowledged its new path. The beam would pass within a hundred metres of the resonator's radiator field. Close enough to demand a warning on any honest plot.

"Put the beam on control's collision layer," she said.

Sena complied. The layer showed empty space.

"They've removed it," Sena said.

"Or their cage solution can't see what the anchor moved."

The distinction mattered. A lie had authors. Blindness could kill without one.

Kessa restored the skiff channel. "Boarding accepted after your pilot matches our manual drift. Cage references excluded."

"Threadbare, cut propulsion now."

"We have cut propulsion."

"Your vessel remains in motion."

"So does yours."

The skiff's blue strobes slid sideways relative to Resonator Two. Its pilot corrected, overcorrected, and fired hard. For an instant the plume bent into a hook around the unseen center.

Nacre control shouted a vector.

The vector arrived late.

Kessa saw the coming collision as a simple load path. Skiff moving inward. Freight collar rotating behind it. Threadbare between both, grapple still attached to the collar. If Sena burned outward, the cable would sweep across the skiff. If she cut the grapple, the released line could strike its cockpit. Three bad repairs, none good enough.

"Reel in two metres," Kessa said. "Roll us port eleven degrees. No translation."

Sena moved before the sentence ended. The tug rolled. Grapple tension drew the freight collar's near edge upward. The skiff passed beneath the cable with its drive plume washing Threadbare's radiator fins.

Heat alarms rose.

A third motion entered the geometry.

The freight collar stopped rotating.

Not gradually. Its thousand tonnes of cut metal held orientation while loose plates and frost continued forward. Kessa's grapple display climbed past its licensed load. The translucent sample pressed so hard against her suit pouch that its crescent showed through the fabric.

"Blow the line," Sena said.

"Wait."

"Kessa."

Across the cupola, darkness lifted again. This time the bent stars traced a broad curve, longer than the freight collar, passing below it. The shape pressed against the cage with no visible boundary. Resonator Four increased output. Then Five. Then all nine, their supposed six-decimal agreement breaking into separate frantic lines.

Nacre control stopped calling the condition green.

"Cage excursion," a controller said. "All craft clear center plane. Repeat, all craft clear."

The freight collar tipped. Stored grapple load dropped in a smooth release. Sena fired outward and Threadbare answered cleanly. The security skiff followed, too

close and humbled into silence.

Kessa kept her eyes on the moving absence.

It turned the collar away from the tug.

The action could have come from pressure, gradient seeking, or the blind consequence of a body shifting under restraint. She refused the tempting word choice. It would make a mystery feel solved while they still lacked the shape of the question.

Pell sent the raw buffer to her console. Nine cage traces filled the display, each laid over Threadbare's independent clocks. For twelve seconds before the first pull, Resonator Four had sampled an extra gradient and discarded it as calibration drift. Five had done the same. The other stations followed in sequence around the wheel. Control's public trace flattened those differences into one approved line.

Kessa dragged the sequence backward. The discarded gradient did not begin at Four after all. It appeared first in the tug's grapple drum, then at Four, Five, and Six, passing through hardware according to position rather than network order. A physical load had crossed the cage. Somebody's software had renamed every stage of its travel until the event became nothing.

"Save the rejection flags too," she told Pell.

"They're station property."

"So are the reasons we're about to be banned from station property."

Vasken appeared in the cockpit hatch, helmet tucked under one arm. "Half the crew wants to know whether a worker stop still protects us if the hazard sits inside the route."

"It protects us from being ordered to cut."

"That wasn't what I asked."

Kessa faced him. Through the hatch she could see others pretending to secure loose gear. They had signed onto salvage, not discovery, and certainly not a fight with the only authority that could license them anywhere in the Reach. Independence aboard a tug often meant choosing which debt collector named the terms.

"If Nacre revokes the berth, we lose water service and the collar payment," she said. "If the Charter suspends my license, Sena can vote me off the ownership papers under emergency covenant. Any crew member can transfer to the skiff before we move. Nobody forfeits earned share."

Vasken studied her, perhaps waiting for a promise that the problem would remain small. Kessa had used such promises before. They bought useful minutes and poisoned every hour afterward.

"What did you find?" he asked.

She removed the specimen tube and held it where he could see the filament

drawing hooks from the stars. "Material growing through our rail. It closed after I cut it. It responded before the cage admitted any excursion."

His grip tightened on the helmet. "Growing from what?"

"That belongs on the list of things I won't invent."

After a moment, Vasken nodded. "I'll tell them the stop stands."

"No. Tell them what it costs. Then take the count."

He went aft. Sena glanced sideways, expression hidden behind the concentration of manual flight. "You know they'll stay."

"I know what I want them to do. That's not the same instrument."

The vote returned seventeen to two for remaining aboard, with the two dissenters requesting transfer before departure. Kessa logged both names without resentment. A routebreaker who treated fear as betrayal eventually found herself working with liars.

A status message arrived from Nacre control: RESONATOR STABILIZATION IN PROGRESS. WORKER STOP ACKNOWLEDGED. ALL SALVAGE CONTRACTS SUSPENDED.

Then the station shut down its cage power.

One resonator after another dimmed around the wheel. With each loss, the stars relaxed toward their proper places. The corridor mouth narrowed. The grapple line hung slack. Kessa expected the hidden structure to settle with the field that defined it.

Instead, the dark center moved another seventeen metres.

Every independent instrument on Threadbare agreed.

No powered cutter touched it. No collision preceded it. No cage solution could assign the motion to their ship.

Beneath Kessa's palm, Tomis's torque key trembled against the console. The three-beat load passed through the tug once more, softer now, traveling away from them toward the next anchor in the chain.

Kessa opened a shipwide channel. "Nobody gives station control a copy of our raw buffer. Pell, make three physical copies. Sena, prepare to lose our berth."

"What classification goes on the worker stop?" Pell asked.

Outside, Nacre-9 continued moving in the dark after every machine had let go.

Kessa watched the filament bend starlight through her suit pouch.

"Unknown living load," she said.

Chapter 02 — A Route That Moved

Kessa drove a calibration pin through the dead frame and felt the blow stop in solid metal.

The frame occupied most of Threadbare's repair gallery, a stripped grapple cradle bolted to the deck in four places. Its load cells had failed certification nine years earlier. Pell had kept them because failed instruments sometimes told the truth after approved ones learned manners. Blue cables ran from the cradle to Anu Sel's portable clock stack, then crossed the deck to three independent recorders that shared neither power nor software.

"Again," Anu said.

Kessa reset the striker. "You could say please."

"I could also introduce timing error."

The second blow traveled through the pin, cradle, deck bolts, and the scar in Kessa's left palm. A clean impulse. No tremble hid inside it. No measured pause separated it into three parts.

Anu watched the traces assemble across her slate. She had boarded through the waste lock before station security closed the service lanes, carrying two cases of instruments and no change of clothes. Her dark curls remained crushed on one side from a helmet liner. She wore the expression of someone whose worst professional suspicion had finally acquired a specimen and ruined her sleep.

"Hardware response matches the model," she said. "Within two percent."

"Two percent buys a lot of excuses."

"Not seventeen metres."

Sena leaned through the gallery hatch. "Control has offered us breakfast if we surrender the raw buffers."

"What kind?" Kessa asked.

"Administrative."

"Decline on dietary grounds."

Sena withdrew to the cockpit. Since the berth suspension, she had kept Threadbare drifting under cold jets inside a security box six kilometres wide. Nacre control called it voluntary compliance. Two skiffs holding opposite corners gave the phrase visible machinery.

Kessa removed the calibration pin and fitted a flexible coupler to the cradle. "Put yesterday's grapple tension through this."

Anu selected the reconstructed load. A motor beneath the deck drew on the coupler. The cradle flexed. One bolt complained through its washer. The recorders produced a single rising curve followed by the frame's damped shiver.

"No triplet," Kessa said.

"Because a collision did not make one."

"We are testing what did not happen before we name what did."

Anu's mouth tightened. She had spent years being told that the objects she studied belonged to engineering, not ecology. Kessa understood the temptation to seize the first proof and make it pay every old debt. She had felt the same temptation when station records blamed Tomis. Temptation made poor torque.

Pell called from the instrument alcove. "I have the cage log beside our spool."

They crossed the gallery while the dead frame cooled. Hot insulation and citrus solvent hung in the narrow space. Crew members passed them without stopping, each finding work that kept hands busy near the conversation. The vote had held overnight. So had the two dissenters, because Nacre security had refused to accept transfers until evidence control arrived.

Pell spread two timelines across the wall display. The upper line came from Threadbare's local sensors. At 19:14:06, the grapple drum recorded the first of three loads. Resonator Four sampled the gradient a fraction later. Five followed. Six completed the passage.

The official cage log placed a collision marker at 19:14:05.

Kessa looked once, then leaned closer. "That marker wasn't there yesterday."

"It exists in the record control sent this morning." Pell enlarged the metadata. "Target mass impact, freight collar debris. They assigned the discarded beam a contact event."

"The beam never touched us."

"Control's public plot removed it before the skiff approached. Their archive has now put it back somewhere useful."

Anu aligned the lines by independent clock pulse. The collision marker shifted right until it sat after the grapple load. "Their timestamp carries a manual correction of one point four seconds."

"Whose correction?"

"System authority."

"That is a door, not a name."

Pell opened the audit layer. Access returned a blank gray field with a Charter seal. "A door with a guard."

Kessa rested both hands on the console edge. The alteration did not prove why Nacre-9 had moved, but it proved somebody needed motion to follow collision rather than precede it. A controller might have repaired an embarrassing report. A supervisor might have obeyed standing procedure. Neither possibility required a conspiracy broad enough to live in every anchor. Small obedience could carry a lie farther than planning ever managed.

"Can we recreate the correction?" she asked.

Pell shook his head. "Not without the station's signing key."

"Then recreate the physical event. Give the dead frame a beam strike, shift its clock, and show me whether any ordering produces yesterday's three-beat load."

Anu glanced toward the cradle. "You want to test a fraud as engineering."

"I want them unable to call it an argument about metadata."

For the next hour, the repair gallery became a collision rig. Vasken brought a cut length of radiator spar from stores. Jori built a pendulum from a cargo hoist and two safety lines. Kessa weighed the spar, measured the swing, then reduced the strike energy because Threadbare still needed its deck afterward.

The first impact made the cradle ring like an offended bell. One recorder lost contact. A deck bolt stretched by half a millimetre. Kessa replaced it while Anu rotated clock offsets through the recorded data.

Every altered timestamp moved the curve. None changed its shape.

Anu isolated the propagation sequence and projected it onto the cradle. Three points lit along the frame, each corresponding to a sensor outside the tug during the excursion. If debris had struck the freight collar, force should have entered at the grapple tooth and traveled inward. Yesterday's load had reached the drum before the tooth registered tension.

Kessa made Pell reverse the model twice. The result persisted. A force path through ordinary hardware could not begin in the middle and spread toward both ends without an actuator at its origin. The drum held no actuator capable of that motion. Its motor had stood electrically isolated under the worker stop.

"Put the cage positions over it," she said.

Anu mapped Resonators Four, Five, and Six beyond the hull. Their projected line crossed the grapple drum exactly where the load appeared first. The sequence had followed external geometry through ship and cable without respecting their mechanical connection.

Vasken folded his arms. "Space pulled on the drum."

"Changing gradient did," Anu said.

"From the hollow?"

She hesitated. "From the region the cage defines around it."

Kessa appreciated the correction. One day's evidence had not earned them a clean subject. "Save that projection. Include every assumption."

Pell added it to the raw spool. "Control will say our independent clocks drifted together."

"Then we show them a clock they adjusted alone." Kessa pointed to the official collision marker. "Their correction leaves the cage sampling pulse untouched. It moves only the event that explains the pulse. That kind of drift knows what report

it wants.”

A second strike hit off center. The frame twisted and produced two peaks, one from impact and another from a loose bearing reaching its stop. Their spacing varied when Kessa changed the angle. The three loads from Nacre had matched within four milliseconds.

“Again,” she said.

Vasken checked the hoist brake. “Chief, if you need this frame flatter, we own a press.”

“I need it honest.”

“Those cost more.”

The third strike cracked the dead load cell nearest the deck. Its ceramic face opened in a white crescent. Beneath it, old graphite inspection marks showed three dates and two sets of initials. The oldest belonged to Tomis Rho.

Kessa stopped with her wrench against the retaining nut.

She had forgotten the cradle came from their first grapple assembly. Tomis had helped rebuild it during his apprenticeship, before he transferred to Lark-3 because a Charter anchor offered cleaner hours and a routekeeper credential. His initials leaned forward as if hurrying into the next line. He had always marked inspected hardware before wiping the surface, impatient with the sequence but never the result.

Anu crouched beside her. “Do you need another cell?”

“This one is finished.” Kessa set the wrench and turned. The nut resisted, then released with a short metallic cry. “Hand me the brass key from the cockpit.”

“You keep a torque key on a flight console?”

“It keeps the pilot respectful.”

Sena arrived carrying the tool by its worn leather loop. She did not offer it immediately. “Security has changed posture. Both skiffs have crew in suits.”

“How long?”

“They haven't sent a demand yet.”

“Then they are waiting for someone who enjoys paperwork.”

Kessa took the torque key. Brass scales ran along its shaft beside an obsolete diagnostic port no modern calibration bench could read. Tomis had tuned the release spring himself. The tool clicked at a setting a careful mechanic could feel two fingers before it arrived.

She fitted it to the replacement cell. Pressure came into her palm through the same rounded handle Tomis had held while marking the cradle. Work kept the memory from choosing its own shape. He had tightened this bolt. He had signed here. At Lark-3, a report claimed he failed to compensate a fluctuation during a hold. The Charter returned his tools cleaner than he ever kept them.

The key clicked.

Kessa checked the scale. Correct.

Sena watched her rather than the bolt. "You still trust it?"

"I trust what I can test."

"That did not answer me."

"It tightened the cell."

Sena accepted the repair verb and went forward.

Anu connected the new sensor. "Lark-3 had a reported material recoil before its correction event."

Kessa's hand remained on the torque key. "You read the public finding."

"I read every anchor anomaly the ecology program could obtain. Lark-3 registered sequential resonator strain. The report attributed it to operator compensation."

"My brother operated the local board."

"I know."

"Then know this too. We test Nacre. We do not bend Nacre until it fits Lark."

Anu held her gaze. "Agreed."

Pell announced an incoming inspection warrant before either could add a softer sentence and damage the terms.

The warrant filled the gallery display. Interroute Charter evidence officers would board in twenty-three minutes, eight hours earlier than Nacre's first estimate. They claimed authority over the filament, all ship records, every tool coupled to the anchor, and any private archive containing related incidents. The last category appeared in language broad enough to include the memory of anyone aboard.

Kessa read the seizure list twice. "They know about the sample."

"Control saw you tube it," Pell said.

"They know about our local buffers too."

"They requested checksum sync while I copied them."

Anu pointed to the warrant's preservation clause. "If they take the filament into a standard materials lab, they will destroy the response conditions before they identify it."

"If they intend to identify it." Vasken had abandoned the collision rig. "Are we running now?"

Kessa looked toward the cockpit. Their security box lay inside the skiffs' intercept margin. Threadbare could burn hard enough to make boarding ugly, not hard enough to clear Nacre's defense envelope. Running would convert evidence custody into piracy and give control a cleaner story than recoil.

"No," she said. "We preserve what they can overwrite."

Crew spread through the tug under her direction. Pell made physical copies of the spool on isolated ceramic wafers. Jori concealed one inside a food inventory reader, where any search would find it within minutes and feel successful. Sena placed another in the manual star tracker under a maintenance seal applied yesterday. The obvious copy remained in the instrument alcove with complete labels.

Anu kept the filament against her body in a field pouch. "A search will detect the lensing."

"Then we give it to them with a documented chain. Make them sign for a living response if they want to call it scrap."

"You called it living yesterday."

"I classified a load. I did not classify a species."

"That caution will not protect it."

"Neither will a claim we cannot support."

A docking alarm pulsed through the hull. The first skiff moved from its corner. Behind it came a white Charter tender with no station markings and an airlock collar large enough to swallow Threadbare's side hatch.

Pell lowered his voice. "One spool remains."

Kessa turned the torque key in her hand. Its diagnostic cavity dated from tools that stored calibration tables locally. Modern keys streamed everything to certified benches. Tomis had refused replacement because a tool should still know its work when the network went blind.

"How large?" she asked.

"Thirty-two terabytes if I strip video and keep raw gradients, clock proofs, rejection flags."

"The key takes forty."

Pell stared. "That port predates me."

"Most useful things do."

They went to the illicit bench at the aft end of the gallery. Kessa removed the torque key's brass heel cap with a slotted driver. Beneath it sat two contacts, blackened by years of solvent. Pell improvised a bridge from probe leads while Anu cleaned the contacts with a swab.

The transfer began at a rate that would have embarrassed a child's slate.

Docking clamps struck Threadbare's hull.

"Fourteen minutes," Pell said.

"We have six," Sena replied over ship channel. "Maybe seven if their collar sulks."

Kessa opened the bench housing and bypassed its current limiter. Heat rose under her fingertips. The projected transfer fell to nine minutes.

"Any faster cooks the cavity," Pell warned.

"The data?"

"The tool."

She pictured the key returned in a sealed evidence bag after Lark-3. For twelve years she had used it on compressors, grapple cells, berth clamps, and the galley hinge Sena refused to replace. Making it a shrine would have insulted Tomis. Burning it for proof might have pleased him until he saw the workmanship.

"Take it to the edge," Kessa said.

The aft lock reported external pressure. Charter officers requested admission in voices trained to make entry sound complete before the door opened.

Anu set her portable clock stack beside the bench. "Use my thermal sink."

"It may corrupt your reference."

"They are about to seize the reference."

Kessa clamped the sink around the brass body. Frost spread over Tomis's initials near the grip. Transfer time dropped to six minutes and twenty seconds.

Sena spoke to the boarding team. "Your warrant requires the vessel master to verify environmental compatibility. We carry exposed solvent."

A muffled answer came through the hull.

"Then your suits are rated for impatience," Sena said. "Ours aren't."

The inspectors started a manual override.

Kessa watched the progress line crawl. At sixty percent, the key's old diagnostic light came on, amber and unexpectedly bright. At seventy-four, Nacre control pushed a remote preservation command. Every networked recorder in the gallery locked its interface. The dead frame's new cell began uploading without permission.

Pell pulled the bench network cable. "They have station authority through hull service."

"Cut the service bus."

"We lose docking pressure control."

"The Charter tender supplies pressure. Let them own one useful thing."

Vasken opened the breaker panel and dropped the bus. Lights changed to red local strips. Ventilation slowed. The transfer continued on Anu's clock battery.

A cutting tool touched the outer hatch.

Ninety-one percent.

Kessa held the heat sink closed while the torque key trembled between its

clamps. Not three beats now. A continuous vibration came from the overloaded contact bridge. Her scarred palm numbed against the metal.

At ninety-eight percent, one contact went dark.

Pell reached in with an insulated probe. "Don't move."

"I wasn't planning a dance."

He pressed the contact. The progress line completed. A verification cycle began.

The outer hatch opened twenty centimetres before its safety dogs caught. White light entered around the seal. Sena's argument sharpened over comms. Someone outside invoked emergency corridor law.

The key's amber light blinked once.

CHECKSUM VERIFIED.

Kessa broke the bridge, replaced the heel cap, and wiped the contacts. She clipped the torque key to her belt among three ordinary tools. Pell restored the service bus as the hatch dogs released.

Six Charter inspectors entered in white pressure suits. Their leader carried a seal projector and introduced herself as Examiner Vaust. She had a narrow face, tired eyes, and no visible pleasure in the work. Two evidence officers went directly toward the instrument alcove. Another scanned Anu's field pouch and marked the filament without comment.

Vaust read Kessa's worker stop from her slate. "You classified an unknown living load."

"I classified a hazard pending inspection."

"You obstructed station collection."

"I preserved independent clocks after station logs changed a timestamp."

The examiner's expression did not shift, but her eyes moved once toward Pell's wall display. "That allegation will be included."

"Include both versions."

"Charter review determines relevant versions."

There it stood: a repair that discarded the broken piece before measuring it.

Evidence officers bagged the obvious spool, the collision rig recorders, and Anu's clock stack. Anu forced them to record the filament's curvature toward her calibration mass before surrendering it. Vaust signed the observation with reluctance precise enough to notice.

When the search reached Kessa, an officer scanned each tool. The torque key registered as an unpowered brass instrument with an obsolete cavity. He turned it over, saw Tomis Rho's initials, then returned it to her belt.

At the forward cupola, security lights multiplied around Nacre-9. Resonator power had resumed at low hold. The dark center pressed one arc of stars outward

and then settled.

Vaust raised the seal projector. "By authority of the Interroute Charter, Anchor Nacre-9 is closed pending structural review. No local craft may approach the cage."

A red lattice appeared across the cupola display.

She turned the projector toward the tug's controls. "The salvage vessel Threadbare is held as material evidence. Drives, grapples, and external communication will remain under lock. Crew may disembark after individual examination."

Sena stood from the pilot's couch. "A vessel cannot be material evidence."

"Today it can."

Nine remote locks entered the tug's systems. Propulsion grayed out. Grapple controls vanished. The berth vector changed from suspended to impounded.

Kessa felt the torque key against her hip. Inside its brass cavity, the raw sensor spool retained the sequence Nacre had tried to reverse: motion first, collision later.

Outside, the cage tightened around the route that had moved.

Chapter 03 — The Calf in the Anchor

Anu pushed a probe through the filament before Kessa could stop her.

The translucent strand lay suspended between two field forks on Threadbare's illicit bench. It had grown from a shaving Anu removed while the Charter officers documented their original sample. The shaving had measured less than a fingernail clipping two days earlier. Now it spanned the width of the specimen hood and bent the bench grid into shallow green curves.

Kessa caught Anu's wrist. "You said observe."

"I observed the surface. Now I need a response."

"You could ask the thing holding the sharp end."

"The probe has a force limit."

"So do people. We still announce knives."

Anu released the instrument. Its glass point remained inside the filament. No fluid escaped. The material had yielded around it in layers too fine for the bench camera to separate.

Across the repair gallery, a Charter seal covered the lawful materials station. Examiner Vaust had taken its drives and left two guards outside the tug. She had not found the old assay hood built into a cabinet behind the solvent recycler. Routebreakers needed places where unregistered alloys could confess before customs learned their value.

Kessa let go of Anu's wrist. "What did you remove from the sample?"

"Less mass than the scale could resolve."

"That answer belongs to someone stealing."

"I preserved a live response from a destructive chain."

"Better answer. Still stealing."

Anu adjusted the fork field by one tenth of a calibration unit. The filament curved toward the stronger gradient. When she reversed the field, it followed. The change did not happen as a loose object falling across the hood. Tension traveled along its length first, then the whole strand flexed into the new geometry.

Pell watched through a recorder disconnected from every ship bus. "Conductive?"

"Not electrically." Anu switched the field off. "It carries gradient change faster than its visible mass should permit."

Kessa leaned close to the hood. A faint branch had formed around the glass point. It thickened while they watched, making the puncture resemble a knot tied from clear thread.

"Withdraw it," she said.

Anu backed the point out by half a millimetre. The filament clung. She reduced force. It did not release.

"Your limited instrument has become attached."

"I noticed."

Kessa took the manual stage control and rotated the probe rather than pulling. The glass point slid free. Behind it, the opening narrowed from both sides. Two pale lips met. Within twelve seconds, no wound remained under maximum magnification.

Pell lowered the recorder. "Machinery can self-seal."

"So can tissue," Anu said.

"Which did we just see?" Kessa asked.

Anu magnified the sealed area. "Layered contraction, directed material transport, and growth toward damage. Those support tissue."

"Support is not identify."

"You found it growing through a repair seam."

"I have found sealant growing through places its manufacturer promised it couldn't."

Anu looked at her over the hood. "Sealant does not conduct a gravity gradient."

"Neither does any animal in your catalog."

"My catalog covers animals that fit inside instruments."

The sentence left the gallery quiet. Beyond the hull, Nacre-9's reinstated cage sent a low vibration through the tug every nineteen seconds. Charter technicians had raised the hold in careful increments since yesterday. Each increment flattened the independent star plots and made station control sound more confident.

Kessa distrusted confidence purchased by force she could feel through her boots.

"Play the raw load," Anu said.

Pell opened a copy from the torque key. "As data?"

"As a field instruction. Use the forks at one percent."

Kessa studied the filament. "No puncture this time."

Anu's impatience stopped short of argument. "No puncture."

Pell translated the three-beat sequence into gradient changes. The first pulse passed between the field forks.

The strand tightened.

A second pulse made its fine branches align along the hood. At the third, every branch bent toward Nacre-9. The response continued after the imposed field

ended. Three smaller contractions traveled from the strand's damaged point toward its growing tip.

Nobody spoke until the filament relaxed.

Kessa replayed the sequence at half amplitude. The same orientation returned. Random polymer response should have weakened into noise. This looked repeatable enough to survive hostile review.

Anu saved the trace locally. "It recognizes the pattern."

"It responds to a load."

"That distinction keeps getting smaller."

"It keeps us honest."

Anu prepared three control sequences before Kessa could order them. The first repeated the loads at equal intervals instead of the measured spacing. The filament curved with each change but showed no coordinated contraction afterward. The second reversed the original order. Its branches tightened toward the stronger fork, then relaxed in place. Only the recorded spacing produced movement from the healed wound toward the growing tip.

Pell marked the distinction on an isolated slate. "Pattern response without claiming recognition."

"Write orientation response," Kessa said. "Recognition sounds like a mind waiting behind it."

Anu did not argue. She moved a small calibration mass along the outside of the hood. The filament followed before the field forks registered enough change to explain its motion. Fine branches gathered on the approaching side. When the mass passed, they spread again along the strand.

Kessa had watched repair organisms close hull punctures and engineered root mats search for coolant leaks. Those systems consumed stored chemistry. They left residue, heat, or exhausted material. The clear strand grew without any measurable loss from the hood atmosphere.

"What feeds it?" she asked.

"Possibly the gradient itself. Possibly matter or field structure we are not measuring." Anu enlarged the newest growth. "The visible filament may only anchor a larger process."

"Do not use that sentence around station management. They will hear unlimited energy and begin writing a claim."

"They already wrote one a hundred and sixty-eight years ago."

Kessa checked the hood seal with two fingers. "They wrote a machinery classification. A claim needs evidence, even when people inherit it."

Anu placed the probe beside the healed site without touching it. "Then consider scale. The branch from your rail continued toward Nacre's center. This piece

preserves orientation after removal. It repairs directed damage. It responds differently to one temporal pattern than to controls with equal total force. A manufactured composite could do every one of those things, but no registered anchor material does."

"Better."

"You want me to sound less certain than the evidence makes me."

"I want your certainty to survive Examiner Vaust."

Pell dimmed the hood lamp. Without direct light, tiny hooked stars appeared along the filament. All of them pointed toward the cage. Kessa rotated the sealed hood ninety degrees. The hooks slid around the strand until they faced Nacre again.

A living inference had begun to assemble from separate tests, each one too small to carry it alone. Kessa could no longer dismiss the shape. She also knew what happened when workers trusted a shape before testing every loaded joint.

"Build a portable fork rig," she said. "If the layers inside the cage share this response, we document continuity from sample to source."

A fist struck the gallery hatch three times, human rhythm without patience. Sena opened it from the cockpit side. Examiner Vaust entered with a station technician and two security officers.

Vaust's gaze traveled from the opened recycler cabinet to the specimen hood. "I sealed all biological material."

"You sealed what you inventoried," Kessa said.

The examiner stepped close enough to see the strand. "Where did that come from?"

Anu answered before Kessa could. "A retained control."

"You retained no authorized control."

"Then your chain has no independent control."

Vaust closed her eyes briefly. Fatigue had deepened the skin beneath them. "Station laboratory reports the surrendered sample as an anisotropic composite associated with anchor maintenance residue."

Kessa pointed at the healed puncture on Anu's display. "Does maintenance residue repair itself?"

"The report does not address repair."

"Did they test for it?"

"The report describes approved materials assays."

Anu made a sound too flat to count as laughter. "They heated it until it stopped moving, then identified the ash."

The station technician shifted behind Vaust. His suit patch named him Bel Marr,

Resonator Six maintenance. Sweat darkened his collar despite the tug's cool air. He stared at the filament as if it had already entered his clothes.

Vaust placed a new order on the bench. "Nacre management has authorized a visual inspection of the inner cage. Routebreaker expertise is required because automatic service arms cannot resolve the displaced layers."

"You sealed our vessel," Kessa said.

"I can unseal tools for a supervised task."

"Why me?"

"Your worker stop remains active. A named routebreaker must either inspect the hazard or withdraw the classification."

There it stood again, procedure arranged until refusal became admission.

Kessa looked at Anu. "Does ecology own a pressure suit?"

"Funding cuts took the fashionable one."

Vaust began to object.

"She comes," Kessa said. "Her instrument found the layer. Sena pilots the service sled. No powered cutter. No automatic grapples. We carry an independent line."

"You are in no position to set terms."

"Then name the engineer who will enter under equivalent exposure and cancel my stop."

Vaust's tired face gave nothing away. Bel Marr looked at the deck.

"Prepare your team," the examiner said.

The maintenance crawl began inside Resonator Six, through a service throat intended for repair drones and workers with narrow shoulders. Kessa went first. Her suit scraped white ceramic scored by generations of graphite marks. Anu followed with a field camera strapped to her chest. Bel came third, carrying the station command slate. Two security officers waited at the outer lock because their armored shoulders would not clear the throat.

Sena held the sled against the resonator with cold jets. Her voice came through Kessa's helmet. "I can see your suit lights. I can also see six Charter weapons pointed at my unarmed tug, which feels excessive."

"Take it as admiration."

"I prefer flowers. They puncture fewer radiators."

Kessa reached the crawl's inner hatch. Frost buried its wheel. According to the maintenance diagram, vacuum lay beyond, then a forty-metre cable run descending toward the cage's central inspection ring. No one had entered since Nacre-9 closed to routine traffic four months earlier.

She chipped frost from the wheel with a brass scraper. The fragments did not

drift when they came free. Each curved inward, following a gradient too slight for her suit to register.

"Bel, when did this frost begin?"

"Condensation after coolant cycling."

"In vacuum?"

"Migration from the jacket."

Anu touched one fragment with her camera probe. Under magnification, translucent fibers ran through the ice.

Kessa felt Bel retreat half a step in the cramped throat. "You knew about fibers."

"We logged contamination."

"How many resonators?"

"I don't have authority to discuss maintenance scope."

"You have authority to crawl behind me."

Vaust spoke from the outer station. "Proceed with the assigned inspection."

Kessa turned the wheel. The hatch seal broke with a puff of crystals. Beyond it, the cage opened into dark.

Resonator Six extended away on both sides as a white structure under bent stars. Nine heavy cables dropped from its inner rim toward the inspection ring, which encircled an absence broad enough to hide a ship. Work lamps mounted along the ring cast straight beams for several metres. Near the center, each beam bowed and disappeared.

Kessa clipped her first tether to the hatch rail and paid out the independent line from her waist. The station's maintenance cable waited beside it, thick as her thumb. She tested both with a gloved pull.

Three faint beats entered the station cable.

Anu's helmet turned toward her. "I felt it."

Bel held still.

"Record locally," Kessa said. "We go to the inspection ring and no farther."

They descended using hand loops along the cable. With every ten metres, starlight distorted more sharply. The cage's dark center gained depth without gaining a surface. Kessa's body insisted something enormous occupied the absence, though the range finder returned uncertain points across thousands of kilometres.

At the inspection ring, frost coated every inward-facing rail. Anu swept her field camera over it. Filaments appeared beneath the ice in braided layers, some fine as hair, others as wide as Kessa's wrist. They did not lie on the hardware. They passed through bolt holes and around support ribs, joining deeper sheets that curved into darkness.

A slow pulse traveled across them.

The layers contracted in order. Near strands tightened first. Deeper sheets followed, making the frost rise and settle. Bent light moved over the structure with the gesture of muscle beneath heavy cloth, though no familiar body plan held at that scale.

Kessa forgot the cold against her face.

Routebreakers had cut this material for generations. Maintenance manuals described lens accretion that fouled resonator faces. Cold-shear procedures told crews where to sever it and how quickly to discard the remains before they distorted tools. She had performed those cuts at eleven anchors.

Her hands remembered resistance no report called tissue.

Anu fixed the camera to a rail. "The outer layer pulses in phase with our sample."

"Because the sample came from it."

"Yes." Her voice softened without losing precision. "That matters."

Bel's breathing grew loud on the channel. "This cannot be inside the service structure."

"It has been inside for years," Kessa said. "Look at the old seams."

The technician pointed his slate toward the nearest braid. A maintenance overlay marked it as obstruction class C, authorized for thermal removal. The date on its first record preceded Bel's employment by twenty-one years.

"We burn that every cycle," he said.

Anu moved between his lamp and the braid. "Do not issue a command."

"I only opened the overlay."

"Your slate has cage authority."

Bel's glove shook. "The structure has breached Resonator Six."

"It grew through Six," Kessa said. "Those do not demand the same repair."

Another contraction crossed the layers. This one pulled the inspection ring four centimetres inward. Kessa's tether snapped tight. Warning glyphs flashed across Bel's visor and command slate.

Station control spoke at once. "Excursion detected. Technician Marr, stabilize local geometry."

Kessa reached for his wrist. "Do not send a hold command from inside the load path."

Bel jerked away. His boot struck the ring. The movement sent him rotating toward the dark center, tether catching hard at his waist. His slate spun on its lanyard.

A red confirmation field opened.

"Bel," Anu said, "close it."

The layers beneath the frost swelled. Three measured contractions passed outward from the dark, larger than the loads they had recorded aboard Threadbare. The ring shifted again.

Bel slapped the confirmation.

All nine resonators fired.

White light entered the dark center. The cage cables hardened into straight lines. Beneath Kessa, the translucent layers crushed inward so abruptly that frost exploded from them in clouds.

Her maintenance tether pulled toward Resonator Six. The independent line pulled toward the ring. Opposed loads folded her across the rail.

"Release station cable," she gasped.

The tether latch would not open under tension. Kessa drove her heel against the ring and brought her emergency shear to the line. Before she could cut, the structure contracted again.

Not a pulse. A recoil.

The inspection ring dropped six metres relative to Resonator Six. Kessa's station cable went taut enough to sing. Its outer braid separated strand by strand. If it failed near the resonator, the released end would cross her suit at cutting speed.

Anu reached Bel and locked one arm through his harness. "Cancel it!"

"I can't override control."

"You initiated local authority."

Vaust shouted from the outer station. "Marr, cancel local command. Control, reduce hold."

No reduction came. Automatic safety had interpreted the contraction as corridor failure. Each resonator drove harder against it.

Kessa pressed the shear jaws around her station cable. The tool carried no power under their terms. She worked the manual lever once. Armor strands flattened but held.

A second stroke cut halfway through.

The cable began to part above her.

Sena's voice cut across every channel. "Kess, your sled track just moved forty metres."

"Cold jets only. Do not couple to cage timing."

"Already disobeying professionally."

Kessa levered the shear a third time. The tether severed at her waist. Its loaded end snapped upward, passed close enough to strike her shoulder plate, and vanished toward Resonator Six. The independent line caught her. Pain ran across

her ribs as the inspection ring dropped again.

Anu and Bel swung below the rail on their shared tether. The field camera tore free and disappeared into the lens-dark curve. Its signal returned from three positions for half a second, then failed.

Kessa hauled herself to the ring. "Vaust, kill Six at local breaker."

"Control refuses a single-station dropout."

"Then give me the name canceling my worker stop while I hang inside it."

No answer came from control.

Vaust gave one. "Examiner Lio Vaust. I accept local authority. Resonator Six dropping in five."

"Drop Four and Five with it or you twist the ring."

"Those stations are outside my command."

"Make your authority larger."

Two seconds passed. Kessa heard voices behind Vaust, procedure colliding with exposed people.

"Four through Six dropping," the examiner said.

The three resonators went dark.

Load left the inspection ring unevenly but slowly enough for Kessa to follow it. She pulled Anu and Bel to the rail. Bel's visor showed a shallow crack across one corner. Anu's camera rig hung empty from its straps.

The remaining six stations continued their hold. In their harsh light, the buried layers trembled. A clear split opened through one braid where force had folded it against a support rib. The edges drew inward, sealing around darkness. No liquid marked the wound. Nothing vocal came through Kessa's suit.

Still, the contraction had carried pain in every mechanical language she knew: withdrawal, protection, damage propagated away from a violent point.

Bel stared at the closing split. "What did I do?"

Kessa clipped him to her independent line. "You obeyed the first alarm."

"That isn't an answer."

"It will have to become one later. Move."

They climbed while Vaust held the three stations dark against control demands. At the inner hatch, Kessa turned for one final look. Frost resettled over the layers. The six active resonators pressed white lines into the bent field. Something compacted beneath them, too broad for her sight and too constrained to withdraw.

Anu remained beside her.

"Say only what you can support," Kessa told her.

The ecologist watched the damaged braid close around its own wound. Her

breath steadied. When she spoke, triumph had no place in her voice.

“Juvenile.”

Far beyond Nacre, too distant for any station signal to arrive without delay, a load entered the cage.

Three beats crossed the dark.

The juvenile answered.

Chapter 04 — Seventy Million Tonnes

Irian Mott began braking Accord of Dust eleven hours before Nacre control admitted the route had closed.

The mass carrier's long truss pointed against its own motion, fusion lamps burning at a fraction of rated thrust. Habitat drums rotated around the spine. Freight barges clung to their docking spars in unequal rows, each loaded according to need rather than symmetry. Every correction flexed eleven kilometres of ship and translated into separate warnings on the bridge.

"Forward water bladder reports mount creep," Daro said from structural control.

"Reduce spin transfer through Drum Four by two percent."

"Passenger delegate will object."

"Give them the mount plot before asking."

Daro sent it. Around Irian, the bridge worked as a logistics pit should: voices low, displays crowded, decisions attached to quantities. No polished command rail separated officers from the people keeping air, food, thrust, and confidence inside usable margins.

Nacre's star burned ahead. The anchor corridor should have appeared as a stable black mouth among duplicated arcs. Instead, the route display showed an amber closure lattice around Nacre-9 and three pages of provisional guidance that contradicted one another.

Irian opened her convoy mass tree. The number at its root had not become easier during the crossing: 70.4 million tonnes of habitat modules, machine seed, water, food substrate, fuel, medical plant, and the structures required to make evacuation more than relocation into a slower death.

The people numbered 410,000.

She kept those figures in separate fields. Mass determined thrust. Names determined what she refused to discard when thrust ran short.

During Sorel's last months, clinic schedules had called one delayed infusion manageable while her wife's body counted the delay differently. Irian had kept names beside reserves ever since, where no efficiency model could turn a person into spare margin.

"Message from Rear Group," communication reported. "They have not entered the corridor. Nacre control directs them to hold at Oriel staging."

"How many souls?"

"Eighty-one thousand, six hundred and four. Two agricultural barges. One waste-cracking module. Hospital cylinder Kindly Argument remains with them."

Irian looked at the convoy plot. Accord and two-thirds of its attached mass had crossed before Nacre-9 closed. The rear group now sat one route away, in a

system with berths for twelve thousand transients and food stores measured in days. Separation placed half the convoy's surgical capacity behind the closure.

"How long can Kindly Argument sustain independent spin?" she asked.

"Thirty hours before bearing heat requires shutdown. Patients can tolerate reduced gravity in cohorts, not all at once."

"Fuel to reposition the rear group?"

"Enough for local separation. Not enough to turn their mass toward another anchor without resupply."

Turning the forward convoy carried its own fiction. At present thrust, canceling their arrival vector would consume twenty-eight hours. Reversing toward any other corridor needed another two days and a fuel reserve Irian had allocated to keeping habitat drums stable during docking. Anyone looking at the plot might see arrows. Irian saw millions of tonnes that would continue along the old arrow after every captain changed her mind.

Nacre control requested they shut down the main drive.

"Decline," Irian said.

Her navigation officer glanced up. "Reason?"

"They issued closure after our committed braking point. We retain thrust until they provide a safe capture solution."

Communication transmitted the refusal. Nacre replied within seconds, which meant a prepared answer.

"Control warns our drive plume may interfere with restricted anchor operations."

"Ask whether their restricted operation prefers collision."

The answer took longer.

A convoy alert opened from Drum Seven. Spin phase had drifted by three tenths of a degree after the braking change. The deviation looked small until projected through a rotating habitat containing forty-two thousand people. Water climbed one wall. Lift cars began arriving above their gates. A school shelter reported children vomiting before local systems recognized the error.

Irian assigned two tug clusters to phase correction. Each tug moved from some other task. Freight Barges Nine through Twelve lost their planned attitude support. A seed vault radiator would run warmer. Every repaired margin opened a cut elsewhere.

"Commodore," Daro said, "passenger delegates want a route briefing."

"In forty minutes."

"They asked for ten."

"They get raw plots now and me in forty. If they want a frightened face sooner, send mine without sound."

Dry laughter moved across two stations and stopped. The bridge knew how little humor the rear group's position allowed.

A direct call arrived from Nacre route authority. The image showed Administrator Cale in a station office designed to imply that chairs still mattered during emergencies. A Charter emblem occupied more wall than the window.

"Commodore Mott, your drive status violates local safety direction."

"Your closure timing violated my braking solution."

"Nacre-9 experienced a material excursion during unauthorized salvage."

"Then give me another corridor."

"Anchors Seven and Twelve remain operational for licensed traffic."

"Seven lacks a receiving throat for our cross section. Twelve approaches through the rear group's current volume. Turning them across us creates collision risk for eighty-one thousand people."

Cale's gaze shifted toward information outside the image. "Your convoy exceeded its declared attached mass by eleven percent."

"We took six habitat modules out of Sable after the elevator unrest. You approved emergency variance at the last route."

"Nacre did not."

"People fleeing a ring shutdown did not become optional when jurisdiction changed."

Irian put the live plot between them. Their braking envelope crossed the station's proposed exclusion zone in red. Kindly Argument blinked beyond Nacre-9, boxed by a closed route and two slow agricultural barges.

"Open the corridor long enough for the rear group," she said.

"Charter inspection has classified the anchor as unstable."

"Then support an exterior transfer of hospital cases and spin hardware through local fusion transit."

"That requires entering the exclusion zone."

"Everything useful appears to."

Cale folded his hands. "A routebreaker lodged the stop. Until she withdraws it, my authority remains constrained."

"Name her."

"Kessa Rho, salvage tug Threadbare."

"Put her on this call."

"That vessel remains under evidence seal."

Irian had learned the sound of institutions using constraints as shields. The routebreaker could be wrong. The closure could still be necessary. Neither truth

excused an administrator who placed responsibility on a worker he had isolated from the decision.

"Then I will speak to her outside your seal," Irian said.

Cale's eyebrows rose. "Her vessel cannot maneuver."

"Mine can."

She ended the call before refusal acquired legal grammar.

The nearest convoy tug carried Irian from Accord's command lock to Nacre's security perimeter. She wore a pressure suit over her bridge clothes and kept the helmet sealed. The tug pilot threaded between attached barges whose separation lights extended farther than some station cities. Their combined drift looked slow. Relative speed still measured in hundreds of metres per second.

Nacre-9 lay ahead beneath doubled stars. Irian could not see the object inside its nine resonators. She saw what it did to everything around it. Work lights bent inward. A disabled salvage tug hung near Resonator Six under Charter clamps. Two security skiffs guarded it from a threat that appeared to lack propulsion.

"Threadbare, this is Convoy Commodore Mott requesting exterior contact," Irian transmitted.

A woman's voice answered. "Define contact."

"Two suits, one hand line, no data coupling."

"Make it three suits. My pilot counts as suspicion."

Irian's tug matched drift forty metres off Threadbare's work rail. She crossed on a line accompanied by a load technician carrying no weapon. Two figures emerged from the salvage lock. Kessa Rho moved first, compact inside a scratched work suit. Sena Ibo followed and clipped herself between Kessa and the tug, an arrangement too deliberate to mistake.

They met at the line's midpoint with Nacre-9 curving the stars behind them.

Irian did not waste air on rank. "My rear group has eighty-one thousand six hundred and four people behind this closure. The hospital cylinder loses independent spin in thirty hours."

Kessa checked the loads on all three lines before answering. "Then don't put them through Nine."

"Control says you caused the stop."

"I invoked it. The thing inside caused the load."

"Thing?"

"A structure that moved after cage power ended. Its filament regrows after cutting. It responds to gradient patterns, and the station used a full hold command while inspectors were inside."

Irian looked toward the anchor. "Are you calling it alive?"

"An ecologist called it juvenile. I call it unsafe to cut until we understand how it carries load."

"People behind us carry loads too."

Kessa's face remained difficult to read through the visor, but one glove tightened around the line. "I know what a closed route costs."

"Do you?" Irian sent the rear-group plot to a local suit display. Names populated the hospital field. Three hundred and twelve critical patients. Seven thousand people assigned to reduced-spin rotations. The rest dependent on supplies distributed through modules never designed to function as a separate settlement.

The routebreaker read without pretending the numbers had changed her facts. That earned more of Irian's attention than sympathy would have.

"What do you need?" Irian asked.

"Twelve hours with independent cage access. No automatic hold. We map where the layers cross each resonator and determine whether a sequential release can reduce the hazard."

"Twelve hours costs the hospital almost half its bearing margin."

"Opening now may cost the cylinder before it reaches this side."

"May."

"Yes."

The blunt agreement left Irian no exaggeration to attack.

Sena spoke from her position on the line. "Control wants Kessa to withdraw the stop so their contractors can restore traffic. Their own technician triggered a hold inside the cage and nearly cut us loose."

"Did anyone record it?"

"Examiner Vaust did," Kessa said. "Whether her record survives review depends on who reaches it first."

Irian considered the geometry. Her convoy could provide instruments, tugs, and a public audience large enough to make quiet editing difficult. It could not create time. Kindly Argument's bearing heat continued rising while they hung under bent stars.

"I can grant six hours," she said. "You get convoy clock reference and remote instruments. At the end, you give me an operational answer. Cross, transfer, or turn. Not a classification."

Kessa's helmet moved a fraction. "Six hours maps perhaps five resonators."

"Then choose the five that decide the route."

"The cage has nine. Loads do not respect convenient fractions."

"Neither do people."

For several seconds only suit ventilation occupied the channel. Irian watched the

line between them bow toward Nacre-9, a physical vote neither woman had cast.

Kessa finally nodded. "Six hours buys a provisional map. I will not certify passage if the other four remain unknown."

"I did not ask you to certify safety. I asked you to tell me which risk I am taking."

"That I can do."

They built terms while hanging between vessels. Accord would lend four field drones, two independent clocks, and a tug to hold cold attitude near the cage. Nacre control would receive every reading live, but no party could alter the stored copies. The convoy would begin moving hospital patients into local fusion craft without waiting for corridor permission. Kessa retained her worker stop.

Sena listened, then said, "You two negotiate like people dividing an air leak."

Irian checked her remaining suit gas. "Air leaks reward clarity."

"Only after the screaming."

A vibration passed through the hand line. Three soft loads reached Irian's glove. Kessa and Sena both turned toward Nacre-9 before the tug's sensors flagged anything.

"What was that?" Irian asked.

"The reason I need all nine stations," Kessa said.

The anchor's dark center shifted. One star arc narrowed. Another opened like a cut under tension. Resonator outputs climbed on Irian's suit plot as control applied more hold.

She watched a route change shape around a population that could not turn.

Back aboard Accord, the six-hour plan consumed the bridge. Field drones detached from Survey Rack Two. Four local tugs redistributed cargo so one could support Kessa. Medical crews started transferring critical patients from Kindly Argument into fusion craft, a journey of days if Nacre-9 remained closed. The hospital cylinder's surgeon refused to move six unstable children unless arrival care could be guaranteed.

"Guarantee receiving beds," Irian told medical allocation.

"Nacre has offered forty."

"We need three hundred and twelve."

"They say local casualty reserve cannot fall below sixty percent."

"Ask every convoy clinic for two beds. Attach names, not percentages."

Daro pointed to a new structural warning. "Drum Four accepted the spin reduction. Drum Seven wants its tug cluster back before the next phase correction."

"How long?"

"Five hours."

The same deadline now held a hospital, a route inspection, and forty-two thousand people's gravity. Irian opened the resource tree and began stripping comfort before safety. Laundry heat stopped. Training spins ended. Two cargo freezers warmed by one degree. The saved power kept Drum Seven's phase controls within margin without the tugs.

Passenger delegates entered the bridge gallery during the reallocation. Marl Quade came first, route-rigger shoulders under a civilian vest, two children listed beside their name in the manifest. Irian gave them the raw plots she had promised.

Marl read Kessa's provisional terms. "Six hours decided by whom?"

"By the hospital's bearing margin and our spin drift."

"Passengers have not consented to an anchor test."

"They are not test subjects. No convoy element enters Nacre-9 during inspection."

"The rear group cannot leave. That makes them part of the risk."

Irian held back the command answer that had served her in route navy. A commodore could not pretend stranded people lacked standing because they sat beyond her immediate hull.

"Then contact their delegates," she said. "Give them direct access to Kessa's data stream. If they request an earlier withdrawal, bring it to me with the consequences attached."

Marl studied her. "You expect consequences to make the choice for them."

"I expect consequences to remain after the choice. Hiding them helps nobody."

The delegate went to communication control rather than the observation seats. Good, Irian thought. Anger that found work wasted less air.

Marl returned twelve minutes later with a live channel from the rear group. Delay through the closed corridor had vanished because no corridor remained to distort it; the signal traveled by local relay to Nacre's far-side repeater, then through a narrow emergency beam the station still permitted. Image quality broke into blocks around three people crowded inside Kindly Argument's engineering bay.

Talar Ume, elected delegate for the stranded habitats, spoke first. "Commodore, control offers us temporary berths if we separate into craft under ten thousand tonnes."

Irian checked the rear manifest. "You have fourteen tugs and eighty-three modules above that limit."

"We know. They presented the offer as capacity."

Behind Talar, the hospital engineer wiped lubricant from both forearms. Her name patch read EVREN SO. A spin-bearing schematic occupied the wall, its

hottest segment orange.

Evren pointed at the plot. "I can hold full rotation for twenty-one hours at present load. Reduced rotation extends that to thirty-four if medical moves ambulatory patients inward. Every transition increases falls and line failures."

"How many cannot tolerate the reduced profile?" Irian asked.

"Three hundred and twelve critical. Another eleven hundred carry elevated risk."

The third person, a surgical coordinator, added names to the risk field while they spoke. Irian recognized the discipline. Counts could numb. Names forced each line to retain a body without pretending emotion solved allocation.

"What can the agricultural barges support if you decouple from the hospital?" she asked.

Talar answered. "Food for six days, water recycling for nine. Waste processing for two if the cracking module stays on your side."

Their convoy had been designed as one moving ecology. Division turned abundance into incompatible pieces. Plenty of water could not replace a failed bearing. Food substrate did not digest waste. Empty clinic berths on Irian's side could not treat patients across a closed throat.

Marl leaned toward the transmitter. "Do your delegates consent to the six-hour inspection?"

Talar looked toward Evren, then back. "We consent to six. Not seven by administrative drift. At the limit, we want a decision even if every option has blood in it."

Irian entered the condition into the command log. "Accepted. Your clocks govern the deadline because you carry the shortest margin."

Nacre control tried to join the call. Talar rejected the request.

Before the image closed, Evren held up a metal cup filled with black lubricant. Fine bright particles moved through it. "This came from the outer race. Delay already has a cost, Commodore."

"I have logged it."

"Logging does not cool it."

"No. But it prevents anyone from calling the failure abrupt."

The engineer nodded once. The channel ended, leaving the bearing schematic on Irian's display beside Kessa's cage map.

Two hours into the inspection, Kessa's first drone reached Resonator One. Its images showed pale layers crossing service hardware under frost. At Three, the filaments thickened around a support rib marked for routine burnoff. At Four, an old shear scar passed through several layers and had regrown along a different path.

Anu Sel's commentary remained careful. Directed closure. Gradient conduction.

Pattern response. Probable tissue analogue. No speech, no claim of thought, no comforting elevation of the structure into something humans would find easier to respect.

Nacre control interrupted every ten minutes with traffic estimates. Food shipments delayed. Passenger routes stacking at three systems. A Charter dispatch demanded restoration under continuity law.

Irian kept the inspection open.

At hour four, Kindly Argument reported bearing temperature six percent above forecast. The cylinder's engineer could preserve spin by venting lubricant around the outer race. Doing so would prevent restart after shutdown.

"Do it," Irian said.

"That spends the bearing."

"It buys the patients time alive. Spend it."

At hour five, Kessa's drones had mapped six resonators, not five. The layers connected across all six in a continuous structure. Every active hold compressed them toward the dark center. No map yet showed a safe corridor state.

Irian prepared to order the inspection closed and commit to patient transfer.

Navigation made a sound that did not belong on a disciplined bridge.

She looked over.

A second amber lattice had appeared beyond Nacre on the planned route to Brine. Anchor Pellucid-2, next receiving point for the convoy, changed from restricted to closed. Its automated notice cited geometry excursion and pending Charter review.

Daro traced the alternatives. Seven could not take their cross section. Twelve intersected the rear group. Returning toward Oriel demanded fuel they no longer possessed after braking. The planned line through Pellucid had vanished before Kessa's six hours ended.

Across the bridge, every route solution turned red.

Irian enlarged the convoy mass tree. Seventy million tonnes continued moving through a system that no longer had an exit.

Chapter 05 — The Wound Pattern

Kessa laid Nacre's oldest maintenance image over the newest and watched the scars meet.

The repair gallery wall showed two versions of Resonator Four separated by one hundred and thirty-seven years. In the first, translucent layers lay close to the inner truss, pale beneath a technician's lamps. Three dark cuts crossed them where thermal crews had cleared bolt access. In the live drone image, the layers had grown thicker and farther around the same truss. The cuts remained, stretched into long sealed ridges.

"Registration error?" Sena asked.

"Four centimetres at most," Pell said. "The ridges miss by less than two."

Kessa rotated both images until the truss bolts aligned. The wounds moved with the hidden structure, not the cage. Their spacing had widened as the layers grew. One scar passed beneath a replacement support installed eighty years after the cut that formed it.

Anu stood with both hands on the image table. "That excludes maintenance residue deposited after the support."

"It excludes that support," Kessa said. "Test every station before you make it carry more."

"You have taught caution enough for one week."

"It still has work."

Threadbare remained under Charter evidence hold, but evidence custody had weakened after Irian placed convoy clocks and drones on the same public stream. Examiner Vaust now occupied the cockpit with a recorder of her own. She had not removed the seal from propulsion. She had stopped objecting when Kessa opened archives the warrant did not mention.

The convoy's six-hour inspection had become forty-one hours of continuous mapping because the second route closure left nobody with a useful reason to stop. Kindly Argument had shut down its damaged spin bearing after completing patient transfers. The rear group remained stranded, alive on margins Irian redistributed twice a day.

Sena called up Resonator Two. "Same positions?"

Pell aligned a fifty-two-year-old burnoff report with the drone pass. Two scars crossed the visible layers beneath a service rail. A third disappeared into the dark center, then reappeared on the far side after the lensing model corrected the image.

"Same," he said.

At Resonator Seven, the oldest available picture showed no layers because the

camera had exposed for ceramic. Anu recovered their edges from bent background stars. The lines formed a shallow fold around every cutter site.

Kessa marked each one.

A diagram assembled beside the images: nine resonators, hundreds of maintenance operations, and a wound field that repeated according to cage position. Thermal clearances cut broad patches. Cold-shear work left narrow paired lines. Emergency holds produced compressed bands around deeper structures no camera could resolve.

If the material had accumulated like frost, new growth should have buried old damage. Instead, the scars enlarged with it.

Vaust watched from the hatch. "Your sample closed a probe wound in seconds."

"Small wounds," Anu said. "These reach through multiple layers. Repair seals the boundary but does not restore original organization."

"Like scar tissue."

"Analogous to it. We do not know the chemistry well enough to claim identity."

Kessa glanced at Anu. "Caution still has work."

The ecologist ignored her with care.

Sena moved the station-age slider backward. "Show me the whole cage without overlays."

Nine images arranged themselves around the dark center. Most showed frost, hardware, and failed light. Kessa had spent her working life treating such pictures as access problems. Where could a cutter fit? Which brace could take load? What material had to leave before a seized mount turned?

Now the clear layers connected across the gaps. Scars formed nine repeated clusters around something the camera never captured whole.

"Put the lens correction on," Sena said.

Pell applied the best model from the convoy drones. Starlight straightened around the cage, then bent across the deeper absence in a broad moving contour. The visible layers narrowed toward one end and spread near the other. No reliable edge appeared, but the field suggested length, curvature, and a raised central form.

A pulse traveled through it.

Stars lifted along the curve and settled beyond it. For an instant the shape resembled a back passing beneath a dark veil.

Sena leaned closer. "Veilback."

Anu frowned. "Do not name it from an optical artifact."

"I named what the picture does to my eyes."

"You named an adult body form without evidence of adulthood."

"I didn't say adult."

"You implied a complete animal." Anu pointed toward the smaller bundles visible near the inspection ring. "We have tissue analogues and coordinated response from a compact developmental structure. The visible structure at Nacre remains a juvenile. A larger life stage may have a different morphology entirely."

Sena folded her arms. "Then the juvenile belongs to something that may become a veilback."

"You are attempting taxonomic blackmail."

"It has been effective on pilots."

Kessa turned the word against the image in her mind. A useful term needed enough shape to travel without claiming knowledge they lacked. Hollow had hidden the structure inside an engineering category for one hundred and sixty-eight years. Animal carried too many assumptions. Veilback described an observed effect and left anatomy unresolved.

"Log it as a field term," she said. "Veilback for the unknown larger form. Juvenile or hollow for Nacre until evidence changes."

Anu looked offended by the compromise, which suggested it divided the available errors fairly.

Pell added the term to their local notes.

Kessa returned to the wound map. "Nacre alone proves long-lived structure under repeated damage. It does not prove every anchor holds the same thing."

"The cage design repeats," Vaust said.

"So does bad procurement. We need other ages."

Route maintenance archives held the answer behind contracts, local formats, and professional embarrassment. Kessa sent a narrow request through the Routekeepers' Union: exterior cage images, any anchor, any year, raw if possible. She did not mention biology. She asked whether their old burnoff scars moved between inspections.

The first reply came from Brine eighteen minutes later. A routekeeper named Orra Senn sent nine images and a note: Thought our registration had slipped for six years. Charter calibration says nominal.

Tern supplied a service scan from before its last refit. Pell aligned it with a recent public navigation survey. Three ridges had migrated outward through hardware while retaining their spacing.

By the third hour, images arrived from eleven anchors. Old cages showed fewer scars and wider clear layers. Newer cages displayed tight bands where resonators pressed closest. Anchor age changed the amount of visible injury, not its arrangement. Every scar corresponded to a standard maintenance or hold position.

Orra Senn opened a live union channel from Mica Hand while Brine's archive

continued uploading behind her. She wore a cutter harness with one shoulder unfastened and kept glancing toward a local cage plot outside the image.

"Your request stirred up half the Reach," Orra said. "Nobody likes discovering an old calibration problem might have been accurate."

"Show me the earliest clean image you trust," Kessa said.

Orra projected Brine's commissioning inspection. The cage had operated for only eleven months. Pale fibers crossed Resonator Three in a loose fan without visible ridges. A second image from year nine showed the first burnoff line. By year thirty, the cut had widened into a dark seam whose ends turned away from the resonator face.

Anu traced the changed growth. "Repair diverted around the injured area. It did not restore the original path."

"We called that preferential deposition," Orra said.

"Because the manual did," Kessa replied.

"Because it let us cut the new path without asking why the old one stopped."

The next union caller worked at Hallowglass, one of the youngest anchors in the network. Its visible layers carried only two narrow scars, both created during mandatory acceptance tests before the corridor opened. No freight had yet passed when human crews made the first wound.

At Pilgrim's Rest, age one hundred and sixty-two, the inner photographs showed so many overlapping ridges that Pell could not separate individual cuts. He used work orders to assign likely dates. Scar thickness increased after every high-strength hold, creating compressed shelves across the underlying layers.

"Maintenance damage and hold damage differ," Kessa said. "Cuts leave directional seams. Holds crush whole bands against the cage."

Anu added colored marks to the diagram. "Both persist. The tissue grows around them, not through them."

A routekeeper from Pellucid-2 joined without video. "Our anchor closed after it produced the Nacre sequence. Charter control has ordered full hold until a cruiser arrives."

"How strong?" Kessa asked.

"One hundred and twelve percent of service limit."

"Your coolant bus will not carry that for long."

"We said so."

"What did they answer?"

"That continuity authority accepts material risk."

Kessa looked at the scars gathered around Nacre's wheel. Material risk meant hardware in Charter language. The phrase had no place for tissue because the category excluded it before anyone measured harm.

"Save your local clocks outside the station network," she said. "Do not cut any layer while the hold remains active. If they order a burn, demand a named engineer under equivalent exposure."

"You think it can happen here?"

"I think I don't know why both juveniles moved within days. That uncertainty argues against adding force."

The caller disconnected to copy logs.

More images arrived. Some routekeepers apologized in their covering notes, as if Kessa held authority to forgive work she had also performed. Others defended each cut with the conditions visible at the time. A fouled radiator could cook a station. A blocked service rail could prevent rescue. The wound map did not erase those dangers. It showed how an institution had solved them repeatedly by injuring the same hidden body and renaming every reaction as obstruction.

Sena sorted the notes into technical categories instead of confession. "If guilt gets its own folder, nobody will open the load data."

"Put operator statements beside the relevant work orders," Kessa said. "No separate absolution."

Anu glanced between them. "You both assume the union will accept the biological finding."

"They will accept scars that match their tools," Sena said. "The name can arrive later."

A diagram from an abandoned training cage showed the standard cut zones as nine red wedges. Pell laid those wedges over Nacre, Brine, Tern, Hallowglass, and Pilgrim's Rest. The pattern covered nearly every mapped ridge. What remained clustered at hold boundaries.

Kessa had wanted a comparison strong enough to survive hostile review. The result carried something harsher than a single altered report. No secret committee needed to coordinate a wound repeated across a century. Manuals had done the work. Shift training carried it. License exams rewarded the cleanest injury.

She found her own marks inside that history.

Kessa had performed some of those operations herself.

She found her work at Merrow-2 in a seven-year inspection series. Her cutter marks appeared as two clean lines near Resonator Eight. She remembered the job: a stubborn translucent obstruction wrapped around a coolant branch, the material flexing away from her first cut and fouling the tool. She had changed angle, increased field pressure, and finished ahead of schedule.

The later image showed a thick ridge grown around both cuts.

Sena saw her initials in the work record. "Kess."

"Mark operator verified."

"You don't have to make yourself evidence."

"I already did the work."

Kessa logged the cut angle, pressure, and her own certainty at the time that she had removed inert accretion. The admission did not restore anything. It prevented grief from turning the map into a story where harm belonged only to strangers.

Anu placed Merrow beside Nacre. "Different juvenile, same cage injury."

"Likely."

"Your caution has become decorative."

"It is holding the word likely in place."

Another archive packet arrived without a sender. Its wrapper used a Routekeepers' Union relay, but the internal format belonged to the Charter's old fault system. Twelve anchors. Thirty-four hold events. In each, resonator strain propagated around the cage in three measured loads before control flattened it into a single excursion.

Pell isolated the oldest event. "Lark-3."

The name cleared space around Kessa.

She touched the torque key clipped beside the image table. The raw Nacre spool remained inside its obsolete cavity. Tomis had also stored local calibrations there, old fragments Pell had ignored while extracting the recent data. If his Lark tools had synchronized with the fault board, the key might retain more than factory tables.

"Open the cavity image," she said.

Pell brought up the directory. Most files carried unreadable names encoded by an obsolete diagnostic suite. Kessa recognized Tomis's habits inside the disorder. He named working files after torque settings so supervisors browsing a tool would see routine numbers. A cluster labeled 42N appeared on the day Lark-3 failed.

Sena put one hand against the table. "You have used that setting since."

"The key never overwrote old fault buffers. It added calibration blocks."

"How much is in there?"

"Twelve years of reasons to maintain old tools," Pell said.

Kessa opened the first block.

A routekeeper board appeared in fragments. Local time. Resonator outputs. Tomis Rho's operator credential. The public finding had summarized these minutes as escalating compensation error during an unexpected fluctuation. Kessa had read that sentence until its words lost edges.

The raw trace began with three loads.

Resonator Three sampled first. Four followed, then Five. The pattern crossed the cage according to position, just as Nacre's pulse had crossed Threadbare. Tomis

reduced hold by eight percent. The structure relaxed. Automatic corridor control restored the pressure without his approval.

A text entry flashed beside his credential: UNCLASSIFIED INTERNAL MOTION. REQUEST TRAFFIC STOP.

Kessa's scarred palm flattened on the table.

The next block showed Charter control rejecting the stop because traffic occupancy exceeded the local operator threshold. Tomis tried again under evacuation authority. His message included a projected service-ring shear and ordered three work crews out.

The public finding claimed he increased compensation.

The raw command showed him reducing it a second time.

Automatic hold overrode him again.

No one in the gallery moved. The repair systems hummed behind the walls. Somewhere aft, a crew member dropped a tool and cursed, unaware that twelve years had changed shape in the forward compartment.

Pell read the checksum twice. "This came from his key at Lark. Local signatures match the station format."

Vaust stepped into the gallery. "Let me verify."

Kessa blocked the table with one arm. "On an independent machine."

"You need Charter authentication."

"I need a copy you cannot replace."

Vaust met her gaze. "Then make three before I touch it."

The examiner had earned that much inside Resonator Six. Kessa let Pell prepare the copies.

Anu aligned Lark's first three loads with Nacre's recorded pulse. Timing matched within the tolerance expected from different cage dimensions. The smaller tremble inside each beat appeared in both. At Lark, Tomis had labeled it moving strain source. At Nacre, the juvenile's filament reproduced it under the field forks.

His fault signature did not show operator error. It showed an animal structure responding to a distant load while automatic systems forced it to remain fixed.

Kessa read his evacuation request again.

Sena stood beside her, close enough for shoulders to touch but did not offer contact. "He saw it."

"He saw a load path."

"He tried to clear the crews."

"Yes."

The repair words held. Barely.

Vaust completed her authentication. "The command record conflicts with the official finding."

"Say his name," Kessa said.

The examiner looked at the credential. "Tomis Rho issued the reduction and evacuation request. Automatic control reversed him."

Anu saved the statement with Vaust's seal.

Kessa turned away before anyone mistook stillness for permission to comfort her. The wound map covered the wall: Nacre, Brine, Tern, Merrow, Lark, and seven other anchors. Different juveniles carried the same marks. Different workers had made them under one procedure. The system had called every response drift until drift became fatal.

Irian's request indicator waited on the communication slate. The commodore needed an operational answer, not a classification. Kessa could not yet provide a safe way through Nacre. She could provide the cost of forcing it.

"Build a release packet," she told Pell. "Raw images first. Registration method. Scar map. Sample controls. Lark command blocks. Vaust's authentication uncut."

Vaust stiffened. "Charter evidence cannot enter a public packet during active review."

"Then remove your seal and leave your spoken verification."

"That does not cure disclosure."

"It cures the part where we pretend time will wait for review."

Examiner Vaust looked toward Nacre-9's live field display. Resonator loads had risen six percent since morning. "Send the technical packet to Commodore Mott under emergency navigation privilege. The union receives maintenance comparisons without my sealed authentication."

Kessa shook her head. "The union receives Lark too. Routekeepers need to know automatic hold can reverse a worker stop."

"That release may cost your license."

"The license already instructed me to cut living material."

Anu corrected quietly. "Probable living tissue."

"Put probable in the packet."

Vaust understood that Kessa would transmit with or without her. She added a narrow evidence note stating that the original files remained under dispute but checksums matched available Charter formats. It protected the examiner less than silence and the truth more than Kessa expected.

They sent Irian the complete case first. The mass carrier acknowledged receipt with convoy clock and redistributed the packet to six independent stores. Kessa watched the copies spread beyond Nacre's ability to seal them.

The Routekeepers' Union received the same evidence twenty seconds later.

Brine confirmed. Tern confirmed. Then local crews across the Reach began requesting their own raw hold logs.

Nacre control entered the channel. "Routebreaker Rho, cease unauthorized transmission and surrender ship communication."

"Communication carries convoy safety data."

"You have distributed unverified biological claims."

"I distributed photographs of our cuts."

The distinction left control silent for four seconds.

A warning rose from every cage monitor at once.

Kessa turned to the wall. Resonator One exceeded its normal load band. Two followed before control could respond. Then Three, Four, and Five climbed together. The juvenile's hidden contour sharpened beneath the star field.

"Pulse?" Sena asked.

Anu checked the gradient trace. "Not yet. This originates locally."

Six rose. Seven and Eight took load hard enough to trip coolant alarms. At Nine, the inner support moved eleven centimetres toward the dark center.

Control applied more hold.

"Stop tightening it," Kessa said.

No one answered.

Across the image wall, every old wound line drew taut. The structure beneath Nacre's cage expanded against its restraints, not toward one gap or one damaged station. It pushed against the full wheel.

All nine resonators began to move.

Chapter 06 — Charterman's Law

Halvek Enro watched three relief routes close while Continuity crossed into Nacre.

The closures appeared on the command wall as amber rings. Nacre-9. Pellucid-2. A local anchor near Brine that had reported no structural fault until routekeepers received Kessa Rho's packet and inspected its inner cage. Traffic projections spread around each ring in red branches, every diversion adding mass to another corridor.

"Recompute with priority cargo separated," Halvek said.

His navigation chief stripped passenger and bulk freight from the model. Medical loads remained. Food substrate remained. Coolant cultures for Sable's orbital ring remained. Even that narrow traffic exceeded available capacity at two receiving anchors within six days.

Continuity held steady under fusion braking. The cruiser had crossed from Orison Gap with nine cutters distributed behind it, a formation designed to place Charter authority within one rapid route of any threatened system. Now fixed routes disappeared faster than the force could arrive.

"Population under direct continuity risk?" Halvek asked.

"Eleven point eight million across Nacre, Brine, and Sable," Analyst Orem said. "That excludes the emergency convoy. Commodore Mott carries four hundred ten thousand in-system, divided by the Nacre closure."

"Do not exclude them."

Orem corrected the field. The number grew.

A second analyst displayed Kessa's evidence beside the traffic map. Pale filament. Repaired puncture. Scar patterns from multiple anchors. The raw Lark record carried an examiner's limited authentication and enough independent copies to make seizure a matter of control, not erasure.

Halvek disliked that distinction. Law functioned poorly when evidence outran custody, but reality often did the same.

"Begin with the strongest claim," he said.

Ecology specialist Venn Cor answered. "The translucent anchor material shows directed repair and coordinated response to gradient change. It persists across the lifetime of a cage. Repeated wounds alter later growth. Those observations support a living structure."

"Support or prove?"

"Support strongly. We lack a complete body boundary, energy budget, reproductive observation, or comparative specimen."

"The term juvenile?"

"Inference. Developmental growth patterns make it plausible."

"Veilback?"

"Field term coined from lensing. No evidentiary value."

Halvek moved to the Lark record. "Operator action?"

A fault auditor enlarged the command sequence. "Tomis Rho reduced hold twice and requested evacuation. Automatic continuity control reversed both reductions. The public finding attributed escalation to operator compensation. That attribution conflicts with the raw commands."

"Can the raw record have been altered inside the torque key?"

"Not without breaking station signatures we have verified."

"Then correct the operator finding."

Several people around the command table looked up.

Halvek did not mistake institutional liability for factual uncertainty. "Issue a provisional correction under my seal. Tomis Rho did not increase the hold. The automated system did. Notify his surviving family before public posting."

"His surviving family released the file," Orem said.

"Notify her anyway."

The correction entered the legal queue. It would anger the station authority that wrote the first report and weaken Charter defense if any death claims reopened. Neither cost changed the command trace.

Halvek placed both hands behind his back. "Now show me a safe route state."

No analyst answered.

Venn Cor selected a model of Nacre-9. "Rho proposes mapping all nine resonators before further cutting. Her evidence indicates holds injure the structure."

"That does not answer the question."

"We cannot yet model release."

"Can the corridor pass traffic under present hold?"

"Mechanically, perhaps. Biologically, continued operation may cause harm."

"May the structure release under traffic?"

"Yes."

"Consequences?"

"Unknown. The observed motion displaced local objects and distorted service geometry. Greater release could collapse the corridor or produce local shear."

Halvek looked at the traffic wall. Food convoys waited beyond two systems. Sable had restored one elevator after unrest near its ring and depended on route imports for bearing composite. Brine exported substrate to habitats that kept only

nine days in reserve. Nacre fabricated pressure skins for four smaller colonies.

A living inference did not make those dependencies imaginary.

"Give me probabilities," he said.

Venn Cor shook her head. "The sample size does not support them."

"Then bounds."

"Worst case under forced release includes loss of nearby ships, resonator stations, and local orbital structures. Worst case under continued restraint remains unbounded because we do not know the life cycle."

"Best case?"

"Present motion settles. The corridor remains usable while study continues."

The answer described hope without giving it a number. Halvek had commanded too many relief schedules to confuse an available best case with a plan.

A signal officer reported that six routekeeper crews had refused thermal maintenance until local tissue inspections finished. Two cited Kessa's packet. Four cited worker exposure. The Routekeepers' Union had not declared a general stop, but local decisions were producing one by increments.

"Open the shortage board," Halvek said.

Cargo classes filled the wall. Brine substrate to Nacre: delayed. Nacre pressure skins to Sable: delayed. Antineoplastic cultures for three habitats: delayed. Reactor salt for Oriel staging: diverted through a route with one-third the freight throat. Every line attached to inventories, consumption rates, and the date when inconvenience became mortality.

One cell showed famine relief contingency.

Halvek selected it before anyone could hide it in a broader category.

The command room around him remained aboard Continuity. For an instant his hands remembered another rail, thirty-one years earlier, on a relief carrier called Tamar's Mercy. The route to Caud had closed after a resonator fire. Command expected repairs within twelve hours. Halvek, then a logistics lieutenant, had approved holding the grain fleet in place rather than burning fuel toward a slower corridor.

Twelve hours became four days.

Caud's receiving inventories had looked adequate at system scale. They were not distributed. Two orbital farms held reserves behind failed transfer spines. Surface towns received allocations through one elevator that could not carry food down quickly enough. The numbers died in different columns before people did.

He remembered fixing a throughput formula while a field medic read settlement names over the channel. He remembered choosing which ships carried children already sick enough to survive acceleration. He remembered a cargo master asking whether emptying seed grain counted as rescue or delayed murder.

When the route reopened, the final toll reached 830,000.

The inquiry blamed resonator maintenance, local hoarding, late evacuation, and inadequate reserves. Every finding held truth. None reduced the dead.

Halvek had learned one lesson that survived every argument over responsibility: a closed route killed outside the frame of the closure.

"Marshal?" Orem asked.

He returned his attention to Nacre. "Show reserve distribution, not system totals."

The shortage board divided into habitats and districts. Brine's six million did not starve together. The outer agricultural cylinders could feed themselves. Dense processing habitats depended on daily substrate transfers. Nacre's fabrication stations held food but lacked long-duration waste capacity. Sable's surface had storage; its orbital workers did not.

Consequences acquired locations.

"Assume all three closures last thirty days," Halvek said. "Prioritize transfers that prevent local reserve cliffs. Suspend luxury cargo. Offer civilian carriers full Charter indemnity for relief diversions."

"Funding authority?"

"Continuity emergency article."

"That article has never covered biological closure."

"It covers interruption. The cause can wait for lawyers."

Orders moved outward. They bought days. Days mattered, but they did not restore the network.

Captain Jalen Vorr of Cutter Two joined the command table by projection. Two other cutter captains appeared beside him. Their ships held station at Pellucid and Brine, where routekeepers refused stronger holds without signed authority.

Vorr spoke first. "Local crews ask whether we will compel operation."

"Not until we establish a controlled procedure," Halvek said.

"Pellucid's hold runs at one hundred and twelve percent. The routekeeper chief says coolant will breach within eighteen hours."

"Reduce to rated maximum. No thermal cuts."

"The juvenile may move."

"So may a failed resonator after coolant loss. Keep the hardware inside known limits."

Captain Esch at Brine asked, "Do we recognize Rho's life classification?"

"We recognize evidence of a potentially living structure. That does not settle route authority."

"Workers hear those as incompatible positions."

"They are inconvenient positions. Incompatibility requires proof."

Esch looked unconvinced. Halvek allowed it. Command did not require every officer to feel certainty. It required them to know which uncertainty governed action.

He brought up Tern Junction. Three anchor cages occupied an uninhabited system with a sparse service spindle and no planetary population. Traffic could divert before entry. One cage, Tern-3, had already been decommissioned for throat instability and retained complete resonator hardware.

"We will conduct a controlled experiment at Tern," Halvek said. "Cold-shear procedure under instrument saturation. No civilian traffic. Remote crews where possible. Rho performs the cut because she has direct experience with the material and raised the hazard."

Venn Cor objected. "Her current evidence argues for observation before cutting."

"We need an operational result. A controlled cut can test injury response and corridor release."

"Only if the conditions match her proposed method."

"She has not proposed a complete method."

"She requested mapping without automatic hold."

Halvek enlarged Tern's cage. "We cannot permit an unbounded release while crews occupy the service spindle. A safety hold remains available."

The ecologist's face tightened. "A hold may contaminate every observation."

"Then instruments will record the contamination."

Captain Vorr nodded once. "My cutter can project local hold from outside the debris plane."

"Prepare to support. Do not activate without direct command."

Halvek assigned two additional cutters to traffic exclusion and rescue. He ordered uncrewed tugs positioned at likely drift vectors. Medical pods would stand outside the cage plane. The plan accumulated redundancies until every known failure had an answer.

Rescue Chief Damel put the sequence through a live geometry simulation. In the first branch, the cut released stored lens stress symmetrically and Tern-3's corridor throat collapsed into a harmless dark point. In the second, one side retained topology after the opposite resonators dropped. The resulting gradient threw the service spindle fourteen kilometres before local tugs could answer. A third branch refused to converge because the model treated the juvenile as static mass.

"Remove that assumption," Halvek said.

Damel spread both hands. "Replace it with what behavior?"

"Bounded motion from Nacre."

Venn Cor objected from the ecology station. "Nacre moved while constrained inside an active cage. A release response may exceed that range."

"Then set three bounds. Observed motion. Ten times observed. Structural limit of the rescue formation."

The simulation ran again. Cutter placement survived the first two cases. At the highest bound, one medical pod crossed the projected debris cone before its pilot could burn clear.

"Move rescue outside the cone," Halvek said.

"That adds eleven minutes to casualty retrieval," Damel replied.

"It prevents rescuers from becoming casualties before retrieval begins."

They shifted the pods. One uncrewed tug took the nearer position with a pressure shelter and automated tow line. Halvek then required every worker on the service spindle to carry independent propulsion. Tern's contractor protested the delay and suit inventory. He overruled them.

Traffic created the harder compromise. Closing all three cages for the experiment would cut a relief diversion feeding Oriel staging. Keeping Tern-1 active placed occupied ships within the outer uncertainty band if Tern-3 released asymmetrically.

"Schedule a clean window," Halvek said.

Navigation displayed the queue. "A complete window delays two reactor-salt carriers by nineteen hours."

"Oriel reserve?"

"Twenty-six hours at current draw, less if the stranded rear group takes local power."

Halvek moved the carriers ahead of the test and accepted a four-hour delay to setup. No occupied ship would enter either adjacent corridor after cold-shear equipment armed. The last carrier might still remain inside the receiving corridor when mapping began, but it would clear before the first cut under every certified transit estimate.

Venn Cor studied the timing. "You are protecting the schedule from an unknown animal with a clock derived from known machinery."

"I am protecting people from both sides of the unknown."

"Until one side runs late."

"Then direct command decides. Automatic hold does not."

Unknown failures remained. They always did.

Legal counsel cleared her throat. "Rho's vessel remains impounded. Her routebreaker license permits refusal under active worker stop."

"Her stop applies at Nacre."

"She may argue the hazard class carries to Tern."

"Then we give her access to design the procedure and document every objection. If she refuses under conditions she controls, I will assign a Charter routebreaker."

Venn Cor said, "You want her expertise or her legitimacy?"

"Both, if both survive contact with the work."

He ordered a channel opened to Threadbare.

Kessa Rho appeared in a cramped cockpit under red evidence lights. Sena Ibo sat at manual controls behind her though the tug's drives remained sealed. Anu Sel occupied the edge of the image with a data slate. None looked rested.

Halvek introduced himself. "Routebreaker Rho, I have reviewed your evidence."

"Did you review the cuts or only the closures?"

"Both. The provisional Lark finding will state that Tomis Rho ordered hold reduction and evacuation. Automatic control reversed him."

The routebreaker's face changed by less than he expected. One hand closed around something below the frame, perhaps the old torque key listed in the seizure inventory.

"You found twelve years quickly," she said.

"I found a valid command record. Delay would not improve it."

"And the juvenile?"

"Evidence supports possible living structure."

"Probable." Anu spoke from the edge.

Halvek inclined his head. "Your report says probable. My authority must account for the probability and for the proven dependence of eleven point eight million people on the affected routes."

Kessa looked toward someone outside the image, likely a monitor carrying convoy shortages. "Keeping a corridor open by tightening the cage increases the load. We watched Nacre push all nine resonators."

"Can you release it safely?"

"Not yet."

"Can you certify continued restraint will cause immediate failure?"

"No."

"Then we have two unresolved hazards and active shortages."

"You have one hazard built around another."

"That may be true. It does not produce an alternative route."

Halvek sent the Tern plan. Kessa read it without speaking. Her eyes moved from cold-shear sequence to remote tug positions, then stopped at the safety hold.

"Remove the hold," she said.

"I will not expose crews to uncontrolled geometry without a stabilizing option."

"The cut tells the structure to release. The hold forces it not to. Running both means you test which one breaks first."

"Then specify a threshold below which standby hold cannot interfere."

"No active beam. No automatic trigger. If your cruiser keeps a remote system cold, we can discuss it after I map Tern's layers."

Vorr sent Halvek a private note: Traffic may occupy adjacent corridor during setup. Full cold status limits rescue.

Halvek considered the request. Removing automatic hold would place the decision entirely in human timing. Human operators had failed before. Automatic control had also failed Tomis Rho. Tern existed to separate those facts under measured conditions.

"The beam remains cold during initial mapping," he said. "Activation requires my direct order. You will perform a sequential cut under Charter control."

Kessa kept reading. "And if mapping shows no safe cut?"

"You will submit the finding before refusing."

"That isn't what I asked."

"No. If you refuse after full access, your license will be suspended pending continuity review. Threadbare will remain impounded and may be requisitioned for emergency route work."

Sena leaned into view. "You offer her a choice between cutting and giving you the cutter."

"I offer the worker who raised the hazard authority to shape the test."

"Under a beam she says makes it unsafe."

"Under a beam that begins cold."

Anu lifted her slate. "A biological response may begin before your instruments classify release. Threshold control assumes the cage knows the event better than the tissue does."

Halvek looked at her data. "Then define a biological indicator my officers can use."

"We need the experiment to discover one."

Every answer returned to the same absence: no safe route state, no release threshold, no time estimate for learning. Meanwhile food, medicine, and waste capacity moved toward known cliffs.

Kessa touched the tool below frame and looked directly at him. "I will go to Tern. I will map before cutting. I will put every objection in the work log. If you activate hold while my shear runs, I stop."

"Agreed, provided stopping does not endanger occupied traffic."

"There should be no occupied traffic."

"Tern has three cages. We can close the test corridor. The others may carry diverted relief."

Her expression hardened. "Then your controlled site already has a load you value more than the test."

"I value both."

"That does not make them compatible."

"No. It makes compatibility the work."

Halvek released Threadbare from static impound for escorted transit to Tern. Evidence seals remained on external communication, with a Charter relay carrying approved technical traffic. Kessa objected. He allowed an independent union recorder under Examiner Vaust's custody. Control required witnesses who distrusted one another.

The channel closed without agreement on the larger question.

Outside Continuity's forward ports, Nacre's convoy occupied half the star field. Habitat drums turned. Barges waited on vectors that consumed fuel even while appearing still. Beyond them, the anchor cage held a darkness whose injured layers might belong to a vast animal life cycle.

Halvek accepted that possibility.

Acceptance did not feed Brine or move a hospital cylinder.

He returned to the command table after his analysts left. Only Orem remained, closing shortage files one by one. The young analyst paused at Kessa's packet.

"Classification?" Orem asked.

"Restricted pending Tern."

"The union already has most of it."

"Most is not the same as an authorized conclusion."

Orem waited. Analysts learned which pauses invited honesty and which invited dismissal.

Halvek opened a private directive. Its recipients included Charter evidence control, route communications, and every local station administrator in the threatened chain.

"Findings that support safe operation may be released with methods and limits," he dictated. "Findings that require route closure must include an immediately executable alternative for essential traffic. Until such an alternative exists, restrict distribution to command review."

Orem's hands stopped above the table. "That standard could withhold a true hazard."

"It withholds an incomplete instruction."

"People may read the absence as safety."

"Then local notices state investigation continues."

The analyst looked toward the population field. "And if Tern confirms the structures live but gives no route?"

Halvek remembered Caud's settlement names arriving after every useful choice had expired. "Truth without movement will not keep them alive."

He sealed the directive under continuity authority.

At the bottom, one operative word remained visible after encryption closed over the rest.

SUPPRESS.

Chapter 07 — Cut at Tern

Kessa set the cold-shear cutter against Tern's outermost feed and felt two commands fighting through the housing.

One came from her tool. Its ceramic jaws drew heat away from the resonator conduit in measured steps, asking the field to diminish along a path the hardware could survive. The other came through the anchor cage as a continuous tightening. Charter control called that pressure a safety hold. In Kessa's gloves it felt like somebody hauling a door shut while she removed the hinges.

The beam had begun cold, as Halvek promised. After her first three withdrawal steps, the last passenger spindle reported a delayed exit from the adjacent corridor. Halvek activated minimum containment without taking Kessa's cutter out of the feed.

She lifted the cutter before either side won.

Tern Junction filled her visor with machinery and almost nothing else. Three anchor cages hung around the service spindle, their resonators joined by pale trusses. Sparse dust caught the work lights in thin amber sheets. No inhabited world waited below. No habitat rotated behind the spindle. Halvek had chosen Tern because a failure here could supposedly spend itself on empty space.

His crews had still brought people into it.

More than a hundred route workers occupied the service spindle and its three exterior galleries. Charter security teams held positions in two armored cutters and the control blister. More personnel waited farther out aboard Continuity. Kessa had counted every suit transponder twice before leaving Threadbare.

Sena held the tug six kilometres above the cage plane, close enough to retrieve them and far enough to survive an ordinary dump. Anu watched field response from the repair gallery. Jori and Vasken worked beside Kessa on separate tethers, their boots clamped to Resonator Tern-Beta Four.

Nothing about the load under Kessa's hands felt ordinary.

"Cutter paused," she said. "The cage is adding counterforce during each withdrawal step."

Halvek answered from the control blister. "The hold remains at minimum containment."

"Minimum containment still opposes the cut."

"Our instruments show both systems inside tolerance."

Kessa looked along the conduit. Frost had formed a straight white band before she began. Now it curled around the housing in hooked ridges, following stress no fabrication plan included. "Your instruments average nine stations. My hands are on one."

A Charter engineer named Rusk opened a private diagnostic pane between them. His face appeared in the corner of Kessa's visor, flattened by helmet light. "Local phase error is point zero two."

"Show the unaveraged gradient."

He hesitated.

"Engineer Rusk."

The raw trace arrived. Two lines crossed and separated with every cold-shear step. Her cutter reduced tension across the outer feed. The hold system restored it from the inner ring before the material could settle. Each cycle left a small excess beneath both measurements.

Jori whistled softly. "We're winding it."

"Correct," Kessa said. "Tools off."

Vasken pulled his isolation fork from the adjacent conduit. Jori secured the thermal braid. Across the cage, other route workers stopped in sequence as Kessa's order passed through their foremen.

Halvek entered the common channel. "Routebreaker Rho, explain the stoppage."

"The cut and your hold form a ratchet. We remove local stress. You restore global geometry before the release completes. The excess has nowhere to go except into the hollow."

"You agreed to a controlled experiment."

"I agreed to perform a sequential cold-shear cut. Nobody told me you would pull against it."

"The containment condition accompanied the authorization."

"It accompanied the transport order. That does not make the systems compatible."

Beyond Beta Four, Tern's dark center deformed the service spindle into two overlapping crescents. Kessa had spent three days studying every available trace from Nacre, Lark-3, and the other cages Halvek allowed them to see. The juvenile remained invisible except when frost, debris, or stars revealed the topology around it. Here the absence seemed compressed. Its bent-light outline pressed close to the resonator wheel, then drew inward in a slow contraction.

Three beats traveled through the feed beneath Kessa's boots.

Not loud. Not violent. The first two arrived close together. The third followed after a pause long enough for the cage to respond. Around the wheel, output rose by four percent.

Anu spoke from Threadbare. "That matches the distant component at Nacre. Longer interval because the source is farther along the chain."

"Do not call it a source until you can establish one," Halvek said.

"I called it a component."

Kessa kept her palm on the conduit. The load did not repeat. A smaller trembling continued beneath it, like a cable carrying motion from somewhere beyond sight.

"Remove the hold," she said.

Halvek's reply took four seconds. Tern itself imposed almost no communication delay. The time belonged to people consulting consequences.

"A convoy segment entered the far corridor nine minutes ago," he said. "Four freight carriers, one passenger spindle, two tugs. They have not cleared the arrival throat."

Kessa turned toward the third cage. Tern-Gamma's corridor mouth showed as a narrow field of doubled stars beyond the service spindle. "Why were they sent through during the cut?"

"They were committed before your stoppage."

"You brought live mass inside linked geometry."

"Their originating system has six hours of reserve power. Delay would strand them at a failing port."

Sena broke in. "And now you want their arrival corridor held open through an incompatible severance."

"I want Routebreaker Rho to resume the agreed procedure."

Kessa studied the raw lines. The excess had accumulated across only three preliminary steps, yet the two traces no longer returned to baseline. If she continued, every cut would store more geometry. If she stopped while the hold remained, the juvenile would keep carrying what they had already put into it.

"How long until the passenger spindle clears?" she asked.

"Eleven minutes at present translation."

"Then remove my crews from the wheel."

"The experiment cannot be rescheduled. The Nacre corridor remains closed, and two more route failures are under review."

"We have learned what the experiment can tell us under a hold. It tells us to stop."

A security authorization spread across her visor. It shifted cutter control from Threadbare to the blister. The tool in Kessa's hands armed without her touch.

She ripped its physical bus free.

The cutter went dead. Ceramic jaws floated open against the conduit.

Vasken stared at the loose cable. "That voids the tool bond."

"Send the invoice to Charter safety."

Halvek's voice lost none of its control. "Reconnect the bus."

"No."

"This procedure supports routes serving eleven point eight million people."

"These workers support it with their bodies. I will not let your remote system move my hands."

For several breaths nobody spoke. Kessa could hear suit pumps, the small scrape of Jori's tether ring, and the deeper vibration coming through Beta Four. Halvek's arithmetic had followed them from Nacre. Closed routes meant hospitals without compounds, habitats without food substrate, stations without machine parts. Kessa did not doubt those consequences. She doubted the claim that they excused adding a second unknown to a dangerous cut.

Rusk sent another private trace. The hold had increased by two percent while Halvek called it unchanged.

Kessa marked the rise and pushed it to every worker channel. "All exterior teams, disengage tools. Move toward spindle shelters by tether line. Do not use powered winches."

A foreman on Alpha protested. "Our orders come through Charter control."

"Then ask Charter control whether its hold rose after the stop."

Rusk's face vanished from her visor. The diagnostic pane remained.

Kessa copied the raw trace into every suit and forced it onto the blister's main board. A red margin appeared around the two climbing lines. The system labeled that margin advisory because the averaged cage still reported tolerance.

"Advisory does not move a body," she said. "Beta teams, state your withdrawal path."

Jori answered for their station. "Rail to Junction Twelve. Handline across the service gap. Spindle shelter Beta."

"If Junction Twelve bends out of reach?"

"Cross to the inspection cradle."

"Cradle has room for four. You carry eleven."

Jori looked along the rail as if a second path might appear when challenged. Kessa made him find one. The thermal-braid locker could take two suited workers if they stripped its spools. A maintenance sled parked below the truss could move six without powered guidance. The remaining three would need separate tether pairs along the feed itself.

Alpha's foreman reported a shelter route through the central spindle. Kessa asked him to count pressure doors. He reached three before discovering that one door's local bottle had failed inspection two months earlier. Charter control had deferred replacement because Tern lacked permanent staff.

"Put a portable bottle there now," Kessa said.

"Security has the nearest one."

“Security can breathe from suits.”

The foreman requested it. A lieutenant refused until Kessa put the denial on the shared channel with the raw gradient. Twelve seconds later, two security suits crossed the truss carrying the bottle between them.

Halvek said, “You are consuming the experiment window.”

“I am discovering your empty junction has people in it.”

She called Gamma next. The arrival-side crews had planned to retreat toward the corridor mouth, exactly where the delayed passenger spindle would emerge. Kessa reversed them toward the outer radiator frame and assigned one route tug to hold beside it with engines warm. The tug pilot objected that Charter traffic control owned his vector.

“Who owns your throttle?” Kessa asked.

“I do.”

“Keep that answer.”

Anu added live pulse timing to each withdrawal display. No line promised safety. The overlays showed where a worker could move without crossing a loaded feed, where changing lens geometry might duplicate visual handholds, and which route relied on a powered winch the crews could not trust after a field excursion.

Kessa made every foreman point a gloved hand toward the first physical rail. Speech could survive as theory. A hand aimed at metal.

On Beta, Jori reached for the maintenance sled and found its mechanical release wired shut beneath a Charter tamper seal. “Do I preserve evidence?”

“Preserve breathing,” Kessa said.

He cut the wire. Vasken kicked the sled clear of its cradle and checked the cold-gas bottle. Half pressure. Enough for one crossing if nobody asked it to steer twice.

Rusk returned to the common channel without his image. “I have posted the unaveraged gradient to the blister board.”

Halvek asked, “Under whose authority?”

“Mine as station engineer.”

For the first time, the safety hold indicator showed its actual two-percent rise beside Halvek's command. Workers who had waited for supervisors began unclipping tools.

Across Tern, route workers began to move. Some obeyed Kessa at once. Others waited until their supervisors copied the raw trace. Security personnel left the cutters in powered suits, not to help with withdrawal but to guard the control nodes.

Anu said, “Kessa, the filament response is changing.”

“Direction?”

“Outward. All measured branches.”

The juvenile answered again.

Three loads struck the cage hard enough to flex the feed under Kessa's boots. The first drove her knees against the housing. The second snapped a frost sheet from the conduit and sent it spinning. Before the third arrived, every resonator fired its hold correction.

Stored geometry released through the system in the wrong order.

Beta Four moved sideways.

The station itself shifted less than a metre, but its surrounding lens did not follow as one body. Kessa saw the work lights bend into white hooks. The service spindle seemed to kink at its center. Jori, two metres away, stretched into a narrow reflection and vanished behind a fold of dark.

“Lines loose!” Kessa shouted.

Vasken cut Jori's tether before the changing angle could pull him into the conduit. Kessa fired her suit jets once, aiming for the place Jori had occupied. Her display showed three versions of his transponder. Two were instrument ghosts. The third accelerated toward the spindle with no physical thrust.

Sena moved Threadbare before Kessa called. The tug descended across the cage plane, grapple drums already opening.

Halvek ordered the hold increased.

“Don't!” Kessa drove her isolation fork into the local feed. “Every increment comes back uneven.”

His command reached the stations anyway.

Tern-Beta Two shed its outer truss. A hundred metres of braced ceramic tore away and struck the service spindle. The impact traveled without sound through Kessa's boots, a blunt kick that folded three exterior galleries. Atmosphere burst from the control blister in a silver cloud.

Emergency channels filled at once.

Kessa heard route workers calling suit failures. Security demanded vectors nobody could provide. A cutter pilot reported two engines firing against each other because the star field no longer agreed with inertial reference. Under all of it, the cage carried a long physical groan that her suit rendered through contact audio.

“Threadbare, give me manual grapple authority.”

“Drum one is yours,” Sena said. “Drum two is holding the tug together.”

A targeting line appeared along Kessa's left wrist. She caught Jori's real transponder by watching debris around him. Frost chips curved toward one image and passed through the others. She fired the grapple past his tumbling suit, opened its three teeth, and reeled until one hooked his tether ring.

The line came tight.

Jori spun toward her with his right arm hanging wrong. Kessa clipped him to Beta Four's surviving rail. "Seal status?"

"Green," he gasped. "Arm isn't."

"Vasken, take him inward."

"The spindle shelters are gone."

"Then use Threadbare."

Another shift swept the cage. This one rolled Kessa across the conduit and pulled the grapple line toward the hidden center. Jori cried out as his broken arm struck the rail. Vasken locked both arms around him while Kessa cut their boot clamps loose.

Sena aligned the tug's forward lock along their new fall. It looked impossibly far away, then close enough to touch, then far again as the lens changed. Kessa waited for the work lights to straighten before pushing Jori and Vasken free. They crossed six kilometres in twenty seconds according to her suit clock. Sena caught them with drum two and a burst from the tug's port jets.

Kessa remained on Beta Four because someone still had to stop the local feed.

She reached the manual break and found its ceramic lever fused under hold current. The cold-shear cutter floated beside her on its wrist tether, bus severed but thermal pack intact. She wedged one jaw around the lever housing and triggered the pack mechanically.

Cold crawled across the ceramic. A crack formed.

"Rho," Halvek said. "Leave the station."

"You kept my crews here."

"The hold has lost synchronization. We are evacuating control."

"Release it completely."

"We cannot while the corridor remains occupied."

The far cage flashed. Tern-Gamma's passenger spindle had begun to emerge, eleven kilometres of rotating structure entering geometry that no longer held a stable throat. Kessa saw one end in ordinary space. The other remained stretched across the corridor. Four freight carriers followed as clusters of duplicated lights.

A Charter cutter drifted between Beta Four and the spindle with its engines dark. Its pilot called for tow assistance. Twelve transponders showed aboard. One radiator folded toward the hull under a gradient that treated metal like soft foil.

Kessa broke the manual lever.

Beta Four's output dropped out of the hold network. Stored load rushed toward the remaining eight stations. The cage center expanded against them, visible through a sudden sweep of stars. She had not freed the juvenile. She had only removed one hand from a body still pulled by eight others.

The security cutter started to fall inward.

Sena said, "I can take you or them on this pass."

Kessa looked at the cutter's twelve transponders. "Take them."

"You have ninety seconds of suit thrust."

"I have a truss."

"That truss has ambitions."

"Learned them at Nacre."

Threadbare rolled beneath the disabled cutter. Pell fired drum one across its bow and missed as the lens shifted. He retracted without complaint, corrected by the way loose hull flakes fell, and shot again. The grapple teeth caught a radiator root. Sena burned laterally. For a moment the tug and cutter moved on separate visible trajectories while the line between them curved through darkness.

Then both ships agreed on a direction.

The cutter cleared the juvenile's expanding topology by thirty metres. Its crew came across the emergency channel one by one, reporting injuries and pressure. Twelve living signals stabilized beside Threadbare.

Kessa climbed the damaged truss toward the service spindle. She passed an empty pair of boots still clamped to the rail. A torn suit glove circled a work light. Transponders winked out faster than the rescue board could classify them.

Alpha's foreman called from beneath collapsed ceramic. "We have nine in pressure. Six outside. Our lock won't cycle."

"Cut the inner hinge and push the whole door," Kessa said.

"No cutter power."

"Use suit packs against the panel corners. Opposed pairs."

She talked them through the load while crossing a gap on her tether. Four workers got the door moving. Two lost contact when the spindle bent again. Kessa did not ask their names over the open channel. Names would come when somebody could answer with certainty.

The door opened against the crushed gallery and jammed at the width of a shoulder pack. Pressure remained on both sides, but a broken cable tray crossed the passage like a sprung rib. Nine workers waited behind it. Kessa could hear one of them counting suit oxygen in minutes.

"Opposed packs will not clear that tray," the foreman said.

Kessa studied debris moving past the spindle. Every loose fragment followed a curve that changed when Beta Four flexed. The inspection cradle drifted forty metres above the gallery, still carrying the mechanical pry bars from the evacuation route she had forced Jori to identify.

"Jori, can you release the cradle tools?"

His injured breath came from Threadbare. "Panel is under the rear bench."

Vasken reached it while holding Jori's splint with one knee. A control packet crossed to Kessa's suit. She rejected the cradle's visual location and found its transponder among two ghosts. One short grapple shot caught the tool cage. The line drew a curve around the broken spindle and delivered the cage against her boots hard enough to crack its lid.

She passed a pry bar through the narrow door. "Set the hook behind the tray root, not the middle. Two of you pull. Everyone else stays off the door."

Metal scraped through suit contact. The tray shifted a handspan and tried to return. A worker wedged a second bar beneath it. Another found an emergency hinge pin on the door and drove it into the gap. They built a ratchet from whatever the station had left.

The smallest worker came through first, dragging a pressure bag with three suit bottles. She clipped each bottle to a waiting chest before moving toward the tether line. Five more followed. The seventh had a cracked visor layer and crossed backward so the foreman could watch the seal. Eight cleared.

The foreman remained inside with the last worker, whose left boot had fused to a floor clamp under the field surge.

"Cut the boot," Kessa said.

"Clamp wraps the ankle."

"Cut the suit joint above it and cap the leg."

The worker heard her. "That takes the leg."

"The gallery takes everything in thirty seconds."

No comforting word belonged in the channel. The foreman used a rescue cuff above the knee, flooded it with sealant, and set a utility blade against the joint. Kessa turned the open channel to medical so the worker heard dosage and pressure instructions while metal parted.

They came through together. The foreman carried the capped suit against his chest. The worker screamed once, then spent the rest of his breath reporting a green torso seal.

Kessa pushed both toward the handline. A route tug at the radiator frame reeled them away without waiting for Charter vector authority. The gallery folded inward seconds after their transponders cleared.

Tern-Gamma's passenger spindle finally cleared the throat. Its rotation had slowed, and three habitation sectors reported structural alarms, but it remained one piece. The freight carriers emerged behind it on diverging vectors. Their tugs burned hard to keep them from crossing.

"Corridor empty," Rusk said from somewhere outside the blister. His breathing came ragged through a damaged suit channel. "Marshal, corridor reads empty."

Halvek dropped the hold.

Eight resonators shut down within a fraction of a second.

Kessa felt every stored increment find motion.

The juvenile unfolded.

No body appeared in the human sense. Darkness widened beneath the spindle and carried a surface made from bent stars. The topology rose through the cage, passing between stations that had seemed to enclose it. Trusses tore outward. Dust vanished along curved paths. Kessa's suit clock lost nine seconds, recovered seven, then flooded her visor with disagreement warnings.

A final three-beat load passed through Tern. The first beat broke the service spindle at its middle. The second threw Kessa free. The third opened a black corridor where no fixed route remained.

She tumbled without a tether, suit jets refusing automatic control because every reference looked false. Ahead, Threadbare appeared in four places. Kessa ignored the stars and watched the tug's hot radiator. Heat followed matter more honestly than light in the lens. She fired toward it in three short bursts.

Sena met her halfway with a grapple.

The teeth closed around Kessa's thigh clamp. Drum one hauled her toward the forward lock while debris crossed paths that should have collided and did not. She struck the outer hatch hard enough to empty her lungs. Vasken pulled her inside before pressure finished equalizing.

Jori lay strapped to the deck with his arm splinted. The rescued cutter crew crowded the repair gallery. Anu worked at a console bolted beside the specimen bench, reading the retreating gradient.

"Where did it go?" Kessa asked.

Anu pointed to the forward display. "Open space. Away from all three corridor axes."

The bent-light back moved beyond Tern's broken wheel. It crossed the dust sheet without impact, drawing particles into a pale wake. No cage beam followed. No resonator remained aligned enough to catch it.

Behind the juvenile, Tern's arrival corridor narrowed to a line and disappeared.

Pell began the casualty count from suit records, lock logs, and the blister roster. He spoke each category once. Seventeen route workers had vanished around Alpha and Beta. Twenty-four more signals had ended across the spindle galleries. Charter's partial roster showed four dead from the broken spindle, while eighteen others remained missing in the blister and second cutter zones.

More reports arrived from the far galleries. The numbers worsened as damaged suits stopped repeating old beacons. By the time Continuity established an independent sweep, the total had settled at 63 dead: forty-one route workers and twenty-two Charter or security crew. Survivors remained in every group, but nobody found another living signal beyond the mapped rescue pockets.

Kessa stared at the board until the figures stopped trying to become a problem she could repair. Jori's blood moved in small spheres inside his splint bag. Vasken held the injured arm steady with both hands. Across the gallery, one rescued security pilot pressed his helmet to his knees.

Halvek called from Continuity. "Routebreaker Rho, report whether the cut caused release."

She opened the common channel so every surviving worker could hear her answer.

"The cut and the hold opposed each other. You delayed removal of the hold with occupied traffic inside linked geometry. Every correction stored more load. When you let go, Tern spent all of it."

A pause followed, shorter than his delay before the accident and far longer than truth required.

"I asked whether your cut caused release."

Kessa watched the juvenile diminish into unanchored dark. "The animal left because the cage failed. We do not yet know how to free the next one safely."

Tern's last service lights went out around the severed spindle. With no corridor to bend them, the stars drew back into single points.

Between those ordinary stars, the juvenile vanished. On the casualty board, Record 63 finished writing coordinates beside a suit transponder that no longer answered. Rescue clocks continued counting in the volume where the route had been.

Chapter 08 — The First Breach

Irian watched seven versions of Kindly Argument drift across the logistics pit.

Only one represented the hospital cylinder. The others came from route solutions that had not admitted Tern's corridor no longer existed. Each model carried the same hull number, the same thirty-two thousand patients and dependents, and a different future position. Two placed the cylinder safely beside Accord of Dust. Three sent it through the wrecked service spindle. One left it inside a corridor throat that had collapsed ten hours earlier. The last drew a graceful curve toward Tern's dark center and labeled the outcome STABLE ARRIVAL.

"Remove every automatic plot," Irian said.

The bridge crew stared at her across tiers of workstations. Accord's command deck had been built to manage mass, not uncertainty. Navigation filled one wall. Habitat loads filled another. Between them, six hundred and forty attached modules hung from the carrier's eleven-kilometre truss as boxes of light, each carrying water, seed, pressure, machinery, or people. None could be allowed to become an icon without consequence.

Navigation chief Ko Demir looked from his board to the central plot. "We need a reference solution to remove one."

"We have fixed stars outside the lens, ship clocks, and our own thrust records."

"Those disagree by four hundred kilometres."

"Then print the disagreement."

Irian keyed the convoy channel. "All captains, disable route-assisted navigation. Preserve your local instrument buffers. You will receive manual navigation slates by tug or tight beam. Do not follow a corridor marker unless two independent ships confirm it by direct sighting."

A dozen objections reached the queue before she finished. The loudest came from captains whose vessels had never flown without an anchor solution. Irian understood the fear. Fixed routes had reduced interstellar navigation to alignment, authorization, and thrust. Tern had taken away the first two while leaving every captain responsible for the third.

She expanded the actual convoy geometry.

Accord of Dust and forty-seven attached habitats had cleared Tern-Gamma before the breach. Four freight carriers and their tugs drifted near the broken spindle. Sixty-three vessels remained in Nacre's system behind a closed departure throat, including food barges that supplied half the convoy's mobile kitchens. Another twenty-nine had diverted before entry and now occupied ordinary space between the two route control volumes. They had neither arrived nor stayed behind. Their last corridor impulse had thrown them outside any charted approach cone.

The convoy existed in three pieces. Irian could speak to two with seconds of delay. The Nacre segment answered through a relay path that took eleven minutes each way and could fail whenever Nacre's cage shifted.

A casualty report opened on a side panel. Tern had confirmed 63 dead. Forty-one route workers. Twenty-two Charter or security crew. Irian read the categories once, then minimized them without dismissing the file. She could not command rescue by staring at a number already settled.

"Plot weak habitats," she said.

Load control painted twenty-six modules amber. Their drive collars could correct spin but could not sustain translation without tow. Eight had tug contracts. Eighteen depended on Accord's truss or route arrival machinery.

"Pair every unpowered habitat with a tug."

"We have eleven free tugs," Demir said.

"Then stronger habitat clusters lend theirs. Pair by life-support margin, not ownership."

A freight captain cut into the command queue. "Commodore, my tugs belong to paid cargo."

"Your paid cargo has forty-one days of passive thermal tolerance. Cylinder D-19 loses air processing in nine hours if its spin collar drifts. Choose which invoice you want read at the inquest."

The captain muted himself.

Marl Quade stood at the delegate rail below the bridge stations, one hand hooked through a restraint strap. He had come up from the passenger drums when the first route models began contradicting one another. His rigger's shoulders filled a civilian coat that had never been tailored for bridge harnesses.

"You're moving contracted tugs without a passenger vote," he said.

"I'm preventing immediate pressure loss."

"Say that into the order."

Irian looked at him. "Why?"

"So the loan ends with the emergency. Otherwise the cargo captains will claim you reassigned their equipment for the rest of the voyage, and the habitat delegates will spend the next week fighting over whether to give it back."

The distinction cost six words and might save six days. Irian amended the order. "Emergency tow assignment until independent pressure and spin are secured."

Marl nodded without thanks. They had no room for gratitude performed as ceremony.

The first weak habitat to receive a borrowed tug carried nine hundred glassworkers from Pellin Arc. Its captain had flown spin corrections for twenty-six years and had never commanded free translation. She called Irian with a manual

slate held close to the camera, the paper display trembling in her hand.

"I have the tug on our south collar," Captain Aves said. "Its pilot wants a vector. My board gives five."

"Cover your board."

Aves looked offended. "Commodore?"

"Put a maintenance sheet over every route solution. Keep the slate visible. Which fixed star sits above your spin axis?"

The captain turned toward an off-camera port. "Kered. I think."

"Do not think. Ask your tug."

The tug pilot confirmed Kered and named two dimmer references. Demir marked their triangle on Accord's plot. Irian had Aves draw the same triangle by hand, then place her habitat where its rim crossed the lower star. The mark looked crude enough to belong on a child's lesson card. It also came from a thing the captain could see.

"Now have the tug burn until Kered moves one finger-width from your axis," Irian said. "Stop. Wait thirty seconds. Mark where the other two stars go."

"That does not give me a route."

"It gives you a measured change. Routes have failed us. Changes have not."

Aves relayed the instruction. Her borrowed tug fired for four seconds. The habitat's spin axis shifted with no promise of elegance, but its pressure collar moved away from the debris sheet. After thirty seconds the captain added a second pencil mark.

"I see it," she said.

"Good. Teach the next habitat."

Irian transferred her channel to Cylinder D-19, where air processors had fallen to eight hours of margin. The glassworkers' captain began the same questions before the connection finished. One manual slate passed knowledge faster than a central solution could pass authority.

Along the convoy, stronger clusters released their tugs reluctantly. Latches opened. Tow craft moved between drifting habitats by direct sighting, each small vessel carrying a navigator who could say what the stars had done rather than what route software expected them to do. Passenger channels filled with rumors of total engine failure, Charter attack, and collision. Marl sent delegates the plain order and its limit: emergency tow assignment, immediate pressure and spin only.

By the time the first eleven pairings stabilized, no habitat had gained a path out of Tern. Eighteen had gained another ship able to see where it actually moved.

A warning turned Kindly Argument red.

The hospital cylinder had begun to rotate around a point no longer occupied by an anchor. Its local tugs reported thrust in the correct direction. The main plot

showed their exhaust bending away from the carrier, robbed of useful acceleration by the lens remnant.

“Direct sighting?” Irian asked.

A sensor officer stripped overlays from the cupola feed. Tern's broken spindle appeared against sparse stars. Beyond it, Kindly Argument crossed the field as a long rotating bar, white hospital markings flashing every twenty-eight seconds. Its path curved toward a patch of doubled light where the collapsed corridor had left a closing lens.

Demir measured the drift from three fixed stars. “Closest approach to the remnant in fifty-four minutes. Margin unknown.”

“Cylinder thrust?”

“Spin units only. Tow tugs are at seventy percent and losing leverage.”

The hospital commander's voice arrived strained but precise. “Accord, our surgical drum cannot take another gravity discontinuity. We have six procedures in progress. Recommend you detach the outer recovery wards and concentrate tow on the core.”

The outer wards held eight thousand people.

Irian opened their module list. Postoperative beds, radiation shelter, prosthetic fabrication, three water tanks, and the convoy's largest sterile pharmacy. Calling them outer wards made separation sound architectural. Detaching them here would put eight thousand people into units with no independent translation.

“Negative,” she said. “Maintain full cylinder integrity.”

A new voice entered under Charter encryption. Halvek Enro appeared at the edge of the plot from Continuity, his cruiser holding beyond the debris field. “Commodore, the hospital's trajectory intersects active lens shear. Separate nonessential mass and recover the medical core.”

Irian disliked how quickly his language made murder resemble sorting.

“Define nonessential.”

“Machine shops, long-recovery wards, dependent berths, reserve water beyond survival allocation.”

“Those dependent berths contain people.”

“They contain people whose survival probability decreases if the entire cylinder is lost.”

“Then send your cutters to tow it.”

“My cutters are recovering Tern personnel and securing the failed cage.”

“The cage is gone.”

“The remaining hardware may endanger every vessel in this volume.”

Irian brought the hospital roster beside his face. Names ran past faster than

either of them could read. "I will not jettison slow civilian modules as nonessential mass to preserve your security perimeter."

"You may lose all of them."

"That risk belongs in the rescue plan, not in a label."

She closed his channel before he could place an order through naval precedence. Accord no longer served in the route navy. Irian had spent fourteen years learning that civilian command required more explanation and a cleaner refusal.

"Available carrier thrust," she said.

Engineering answered from three decks aft. "Twelve point four percent reserve if we keep scheduled Brine transfer and spin support. Seventeen if we cancel both."

"Tow geometry for Kindly Argument."

Demir built it manually. Accord could not approach the cylinder as a ship approached another ship. Seventy point four million tonnes of convoy infrastructure stretched along her truss and barges. A turn begun now would take hours to settle. Instead, she could burn crosswise and use the carrier's mass to shift the hospital's relative fall, then send every available tug down the new line.

The maneuver would consume fuel intended for later route corrections. No later route yet existed.

"Prepare a lateral burn at point three standard," Irian said. "Duration six hundred seconds."

Engineering came back immediately. "That spends five point one percent reserve."

"I heard the estimate."

"Thermal recovery leaves us unable to repeat it for nineteen hours."

"Then make this one accurate."

Marl leaned toward the central plot. "What happens to the attached habitats?"

"Every drum feels a lateral load below design comfort and above design politeness. Tell delegates to secure loose mass and stop water transfers."

"People will think we're turning."

"We are turning one degree so a hospital does not fall into a hole."

"Say that too."

Irian added it to the convoy announcement. Across the truss, habitat controllers shut down pumps and locked agricultural carts. Command crew tightened harnesses. Barges reported latches. One cylinder refused the burn because its neonatal ward could not tolerate the projected vibration.

Irian called its captain herself. "You have six minutes to float every crib on shock

webbing.”

“We need twenty.”

“You have six before thrust and fifty before the hospital reaches the lens. Use corridor mattresses under the web anchors.”

“Those are not certified.”

“Neither is the dark.”

The captain accepted.

Manual navigation slates began leaving Accord through courier tubes and tight-beam packets. Each contained the same blank field, three fixed-star references, local clock offsets, and instructions for marking another ship's position by direct sighting. No central route line appeared. Demir hated the absence.

“Captains will draw different maps,” he said.

“They already have different maps. Now they can show us where.”

“Some of them cannot solve a three-body drift without automation.”

“Pair them with crews who can. Put a navigator on every habitat-tug channel.”

The first slate came back from a mining tender. Its hand-marked hospital track differed from Accord's by ninety kilometres but agreed on the direction of drift. A routekeeper cutter contributed a second trace. Three cargo ships added rougher marks. Demir layered them without averaging away the disagreement.

A corridor of probable motion emerged.

Irian pointed to its outer edge. “Place tugs there, not on the nominal center. If the hospital falls faster than predicted, they meet it. If it falls slower, they can burn inward.”

Eleven tugs detached from stronger habitats. Four belonged to freight firms that had objected. Two hauled water bladders and left them drifting under passive beacons. One came from Accord's own docking spine with half its maintenance crew still fastening panels.

Halvek reopened his channel. “Your burn could destabilize the remaining Tern hardware.”

“Your hold already completed that work.”

“This is not the time for accusation.”

“No. It is time for thrust. Clear my projected plume.”

Continuity moved two cutters aside. The cruiser itself held position.

At burn minus thirty seconds, Kindly Argument reported a failure in its near tow collar. One of the original tugs had pulled against a false star reference until the collar bearings seized. The tug remained attached but could not alter its angle.

“Tell them to cut loose,” Demir said.

Irian watched the hospital rotate. A drifting tug near the cylinder could strike an

outer ward during the carrier burn. Keeping it attached would twist the failed collar.

"Can they lock their gimbal?"

"Not remotely."

"Crew outside?"

"Two suited riggers on the collar."

The hospital commander spoke over him. "We can abandon the tug with both crew aboard. Their drive remains functional."

Irian counted time. Twenty-one seconds.

"Riggers return to tug. Blow collar bolts on my mark. Tug burns radial north and joins the outer tow line."

A rigger answered with heavy breathing. "One bolt won't arm."

"Manual striker?"

"On the cylinder side."

Nine seconds.

"Leave it," Irian said. "Everyone secure for thrust."

The failed tug would remain attached. They would have to carry its bad angle through the burn.

Accord of Dust fired lateral engines.

Acceleration entered the bridge as a slow pressure against Irian's harness. The logistics pit creaked around its reinforced joints. On the mass board, six hundred and forty module icons shifted from green to amber as their mounts took load. Water moved inside bladders despite locked valves. One agricultural cylinder lost spin synchronization and recovered under local control.

Outside, the carrier's eleven-kilometre truss bowed by a measurable fraction.

The hospital did not move toward them at first. Its apparent track worsened as Accord changed the reference field. Three navigation programs generated collision warnings based on the discarded route solution. Demir killed them one by one.

"Use the slates," Irian said.

Direct-sighting marks arrived from the tug line. Each reported Kindly Argument crossing a slightly different star pair. Together they showed the cylinder leaving its original curve.

The carrier's mass had changed the meeting geometry. Eleven tugs burned from the outside edge of the predicted corridor. Their plumes made a ragged fan. The hospital rotated into it, carrying the failed tug like a splint tied at the wrong angle.

"Tow contact in ninety seconds," Demir said.

The closing lens brightened.

It had no surface, only a region where starlight doubled and slipped. Tern debris approaching that region accelerated along curves the manual plot could not anticipate. A section of ceramic truss vanished from one side and reappeared as fragments thirty kilometres away.

Kindly Argument passed within the uncertain margin.

Its outer wards stretched on the visual feed, an effect of bent light rather than metal, yet pressure alarms rose across three decks. The surgical drum lost half a rotation. One tow tug crossed behind the cylinder and nearly entered its radiator wash. Another burned dry correcting the line.

Irian held Accord's thrust until engineering called the reserve at seven point six percent spent.

"Commodore, planned duration complete."

"Ten more seconds."

"That takes us below Brine margin."

"Ten."

The engines continued. Direct sighting showed the hospital clear the remnant by eighteen kilometres, a number with an uncertainty larger than itself. What mattered lay in the trend. Every new mark placed Kindly Argument farther from the closing lens.

"Cut thrust."

Pressure left the bridge. The truss rebounded with a shudder felt through deck plates and seats. Engineering began listing overheated units before the burn ended.

Tow tugs brought the hospital alongside over the next three hours. No route solution guided them. Navigators called star pairs and clock marks across open channels. Captains corrected by fractions, then waited to see which geometry held. The failed tug remained attached until a rigger reached the manual striker and broke the last bolt with a steel bar.

When Kindly Argument finally matched Accord's drift, its commander reported six patients lost during spin interruption and thirty-one serious injuries. Eight thousand people still occupied the outer wards Halvek had called dispensable. The sterile pharmacy retained pressure. Every reserve water tank remained attached.

Irian entered the losses without converting them into victory.

Fuel control gave her the new reserve. The rescue had spent enough reaction mass to erase Halvek's offered timetable for Brine and whatever destination followed it. Accord could still turn. She could not do so quickly, and no second lateral burn remained available before the engines cooled.

A tight-beam packet arrived from the Nacre segment. Their route throat had sealed while they waited. Sixty-three convoy vessels, carrying one hundred thirty-six thousand people, now lacked any open fixed corridor to Tern. The

twenty-nine ships between control volumes had found stable ordinary-space drift, but the nearest charted approach lay months away at fusion speed.

Demir placed those groups on the manual plot. "One third," he said.

Irian checked the population and vessel counts. Depending on whether the between-volume ships could rendezvous, the fraction varied by two points. The useful truth did not.

One third of her convoy had fallen outside every fixed corridor.

Halvek requested command coordination. Irian left the request unanswered while she reviewed air, water, and tug assignments for the stranded ships. The manual slates spread across her bridge in dozens of incompatible hands. Each carried a piece of where the convoy had gone.

She ordered blank slates copied to every remaining helm.

On the central plot, Demir removed the last automatic route line. What remained looked less like a convoy than scattered work marks across empty space. Irian fastened her harness tighter and began pairing every mark with another ship that could see it.

Chapter 09 — The Wake Map

Tomis's torque key opened along a seam Kessa had never noticed.

She sat on Threadbare's repair-gallery deck with the brass shaft clamped between her boots. Charter seals covered the outer lock. A security grapple held the tug against Nacre's evidence berth. Every legal tool aboard had been tagged, indexed, and disabled through its network bond. The key remained in her hands because an inspector had classified it as personal memorial hardware.

Tomis would have objected to the word memorial. He had used the key to open compressor housings, strike frozen latches, and cheat old diagnostics into accepting manual calibration. Its edges carried more machine oil than reverence.

Anu knelt opposite Kessa with a probe wire threaded through the hollow shaft. "Rotate left by one tooth."

"There are no teeth."

"Then by whatever amount makes your hand stop arguing."

Kessa turned the collar. A sliver of brass lifted beneath her thumb.

Inside lay a second diagnostic cavity, narrower than the one Pell had used to hide Nacre's raw sensor spool on Day 1. Its contacts had oxidized black. Anu touched the probe to them and brought up a memory map on the specimen bench.

Two archives appeared.

The first held Nacre-9's rejected gradients and station timing. The second carried an unabridged Lark-3 service header dated twelve years earlier. Tomis Rho's apprentice identification occupied the author field.

Kessa stopped turning the key.

Neither woman spoke. Ventilation pushed citrus solvent through the gallery, failing to cover the smell of burned insulation from Tern. The tug's patched drum remained still. Charter impound had shut down spin to prevent crew movement, leaving everyone in berth gravity supplied through the lock.

"How much?" Kessa asked.

Anu counted sectors. "Forty-eight minutes of cage telemetry. Maintenance channel. Local load traces. One complete command log."

"The copy we released had nine minutes."

"Tomis kept the rest here."

The answer cut cleanly because Anu did not soften it.

Kessa connected the cavity to an isolated slate. Lark-3 opened as rows of obsolete diagnostics. The command extract already in Charter evidence had established Tomis's hold reductions and evacuation order. Halvek's provisional correction removed operator error from the finding. This larger archive carried

something the correction did not: physical load before any command.

Three beats crossed the outer resonators seven minutes before the official fault time.

Each carried the same rise, tremble, and release Kessa had felt through Nacre's grapple line. The interval between pulses differed. Lark's beats arrived closer together, compressed by a cage already drawing more power than its public log admitted.

Anu laid Tern's surviving trace beside it. "Do not align by station clock. Align by the first outward filament response."

"Tern lost nine seconds during release."

"Which clock?"

"All of them."

"Then use physical sequence."

Kessa marked the first frost displacement on Tern-Beta Four, the first load at Nacre's fairlead, and Lark's first unclassified gradient. The traces settled into three columns. What had looked like separate failures shared one internal shape.

Tomis's log included a maintenance voice channel.

Kessa muted it before sound emerged.

Anu waited. "We need the timing."

"We have timing."

"We have station response. The full maintenance channel may identify what the crew saw before the command extract begins."

"I heard the extract."

"It begins after the first load."

Kessa's left palm pressed against the old scar. She had accepted the report because it converted Tomis's death into work she understood. An apprentice misread a fluctuation. A senior routebreaker failed to teach him. A cage corrected. The dead could be assigned to causes, and causes could be prevented with better hands.

She restored the channel.

Static filled the bench speaker. Tomis sounded younger than her memory had allowed.

"Lark control, the center is pushing across the outer feeds. This isn't thermal."

A supervisor told him to verify compensation.

"I did. The load came before our correction. Evacuate the wheel."

Another voice called the order premature. Then three impacts struck the recording, spaced at the same interval as the raw gradient.

Tomis said, "Something answered from route north. Get them off the wheel."

An automatic system announced HOLD COMMAND ACCEPTED.

The cage response climbed. Metal failed. The channel ended under noise.

Kessa shut off the speaker without touching the file.

Anu looked at the twelve-year-old trace. "He read it correctly."

"He ordered evacuation."

"Yes."

"The finding says he applied a local correction before authority transferred."

"The command log shows an automatic hold overriding him."

Kessa removed her hand from the key. Brass had marked her palm with a line of old oil. "Save the voice separately. We map first."

Working spared no one, but it gave grief edges.

They needed more than three failures. Nacre, Tern, and Lark-3 could form a pattern because two frightened people wanted one. Kessa opened the archive seizure copies Charter had placed aboard while inspectors searched the tug. Halvek's people had gathered telemetry from every cage that showed an unexplained excursion, intending to prove equipment commonality. They had stored the files on Threadbare's own bench and trusted the impound bond to keep Kessa out.

The specimen bench had never respected network bonds.

Anu routed its microscopy controller through the old diagnostic cavity. The archive opened one station at a time.

They searched all 73 anchors for the three-beat load. Public logs contained none. Raw maintenance buffers retained fragments at twelve anchors because local instruments had classified them as frost shift, cable recoil, clock error, or operator contact. The oldest event had occurred at Sable's inner cage. The newest preceded Tern by less than an hour.

Kessa placed the twelve anchors on a route chart.

Nacre and Tern sat adjacent. Lark-3 lay two nodes behind Nacre on a corridor the Charter had sealed after its failure. Brine, Orison Gap, and Sable curved away along different commercial routes. On the trade map they formed no useful line. Cargo algorithms crossed the Reach by demand, not by physical proximity outside corridors.

"Remove human routes," Anu said.

Kessa blanked trade connections, transit times, and corridor ownership. Twelve anchor positions remained against the Reach's actual stars.

The marks formed a broad curve.

Not a perfect one. Space offered no drafting table. Yet each three-beat event

followed the next by position along that curve, while event timing ignored the short cuts humans had built between cages.

"A failure cascade should follow shared control links," Kessa said.

"Or hardware age. Or common maintenance."

"These do none of them."

Anu expanded the event times. "Treat each juvenile response as a receiving point."

"Receiving what?"

"A changing gravitational field. Do not promote it to communication."

Kessa built a propagation model using the physical distance between anchors. The first attempt scattered the events across six days. The second required impossible speed changes. On the third, Anu corrected for each cage's hold strength. Stronger holds delayed visible response. Weaker cages moved earlier and left cleaner traces.

The twelve points aligned.

A pulse had traveled along the curve. The juveniles had not failed in sequence. They had answered the same migration condition at different times under different restraint.

Kessa stared at the chart. "A wake map."

Anu frowned at the phrase.

"Not a message. A path left by the load."

"That I can tolerate."

She labeled the file WAKE MAP, MODEL 1.

One clean curve did not satisfy Kessa. She broke the model on purpose.

First she removed Lark-3. The remaining points still followed the physical arc, but the timing window widened by nine hours. Next she removed Tern. The model predicted its response within eleven minutes of the recorded first load. Nacre mattered less to the fit than she expected. It mattered more to them because they had touched it first.

"Swap the hold values between Sable and Brine," she said.

Anu did. The sequence failed. Two juvenile responses landed in reverse order, and the model demanded a pulse that accelerated between anchors without a corresponding change in field strength.

"Use public values only."

"That failed before."

"I want to know how."

Published hold records spread the twelve events into a false cascade. The earliest apparent failure occurred at the oldest cage. Later events followed

maintenance dates closely enough to support Halvek's equipment theory. Kessa opened the underlying power draws. Every station had reported lower restraint than it actually applied. The difference increased whenever local controllers received a three-beat anomaly.

"They hid the response by tightening," she said.

"Possibly without knowing what they hid. Automatic correction would do this."

"Someone wrote the automatic correction."

"Intent does not change our timing."

Kessa accepted the correction and returned to the work. They replaced official power with measured draw wherever raw buffers survived. Six anchors had complete records. Four retained partial feeds. Two offered only thermal rejection, forcing Anu to infer resonator load from waste heat.

The wake curve tightened again.

A second test used direction. If the events came from linked control failure, command traffic should lead physical response. At eight anchors, local cable strain preceded the first control packet. At three, station clocks lacked enough resolution. Lark-3 provided the deciding trace: Tomis had marked outward load thirty-seven seconds before Charter synchronization reached the cage.

Kessa listened to that segment without playing his voice. A maintenance stylus scratched against metal. Suit fabric moved. Then the first sensor tone arrived. Those small sounds fixed his body in a place the report had erased.

"Physical before network," she said.

Anu entered the result beneath the chart. "Compatible with one external migration pulse crossing juvenile positions. Still not proof of an adult."

"No. It proves the failure-cascade model cannot explain order without inventing a second clock."

"Halvek may prefer the second clock."

"Then we make him name it."

They saved every test, including the ones that weakened their claim. Kessa added error bars large enough to offend anyone selling certainty. Even with those margins, the twelve anchors remained a chain. Whatever traveled along it did not care which human corridor made cargo fastest.

A knock sounded through the locked repair-gallery hatch. Sena floated on the far side of its narrow window, one shoulder hooked under a berth restraint.

"Security inspection in fourteen minutes," she said. "They have decided the burned insulation might conceal moral intent."

"We need the forward cupola."

"You need a ship that can power its sensors."

Kessa held up the torque key. "Can you give me one?"

Sena's eyes narrowed. "Lawful, quiet, or effective?"

"Effective for twenty minutes."

"That excludes lawful."

She pushed away from the window.

Anu opened the Tern release trace. Its final movement extended beyond the twelve anchors, a gradient tail caught by Threadbare as the juvenile vanished into open space. The tail did not point along any fixed corridor. It curved toward the next point on their map.

"If the juvenile follows the pulse path, what made the path?" Kessa asked.

"Something with a larger effective lens body."

"How much larger?"

"We cannot derive mass from one wake."

"Use cage responses."

Anu objected for six minutes. Then she did it.

They treated every hold correction as a crude measuring instrument. Each cage had resisted the distant field before its juvenile moved. The effect weakened by position, returned in periodic troughs, and grew across the most recent events. Kessa supplied resonator loads. Anu supplied biological limits derived from the Nacre filament. Neither trusted the other's assumptions, which improved the model.

A body capable of generating the measured field would extend its lens topology across tens of thousands of kilometres.

Kessa reduced the scale twice. The data pushed it back.

"Adult stage," Anu said at last. "Candidate only. Not proof."

"Returning along the curve."

"If the curve represents migration."

"When?"

The estimate depended on how much the cages delayed each response. Kessa ran minimum hold, published hold, and measured hold. Published values produced nonsense. Measured values narrowed arrival to a six-day window.

Its center landed thirty days from Day 12.

Kessa checked the arithmetic through a second tool. "Day 42."

"Plus or minus three days."

"Tern did not give us three days of warning before it opened."

"Tern had a Charter hold and an incompatible cut."

The dead entered the room without sound. Sixty-three people reduced to roster files on Halvek's cruiser and damage marks in Threadbare's gallery. Kessa had

made the cut. Halvek had maintained the hold. The juvenile had followed a biological pressure neither of them understood. Causes did not divide cleanly enough to let her step outside them.

Sena restored local power.

The repair gallery dropped as Threadbare's drum began turning. Lights flickered. Somewhere aft, Pell applauded once before Vasken told him to save it for escape.

"Forward sensors for eleven minutes," Sena said over comms. "After that the berth notices our power draw."

Kessa and Anu carried the isolated slate to the cupola. Charter seals crossed both acceleration couches. Sena had cut around hers so neatly that the torn strip still appeared intact from the hatch.

Nacre-9 lay beyond the berth structures, its cage bright under reinforced output. All nine stations projected hold power into the juvenile. Two security cutters patrolled the wheel. The supposedly stabilized center pushed one duplicated star outward by a visible fraction.

Anu loaded the wake map onto the manual console. "If our delay correction is right, the hold does more than suppress motion."

"It stores the difference."

"Biological release continues underneath. Cage geometry keeps dragging it back."

Kessa overlaid Tern's accumulating excess. The curve matched. Every forced correction had increased the energy available when the cage lost control.

Each hold stored more violence for the larger body's arrival.

She sent the model to Halvek under emergency engineering priority. He answered from Continuity within four minutes. His face occupied the central display, composed against a bridge still carrying Tern damage alerts.

"You accessed seized records," he said.

"I accessed my brother's tool and data stored aboard my ship."

"Your ship remains Charter evidence."

"So do sixty-three bodies. Read the map."

Halvek looked past her toward someone off display. "My analysts see an extrapolation built from mislabeled maintenance noise."

"Twelve anchors carry the same three-beat load in physical order."

"Your sequence depends on estimated hold delay."

"Tern measured the delay by killing everyone near the cage."

His expression tightened. "Do not use casualties to substitute for validation."

"Then validate it. Remove one hold and measure the relaxation."

"After Tern, no responsible authority will weaken another cage on your

recommendation.”

Anu entered the frame. “Reinforcement increases stored gradient. That claim comes from your own resonator response, not from animal interpretation.”

“We have millions dependent on corridor stability and no tested alternative.”

“Your corridor stability has begun moving,” Kessa said.

Halvek brought up a new order. Twelve anchor designations filled it. “All cages in the proposed chain will increase reserve power and maintain continuous hold. Local crews will inspect for control drift. Threadbare remains impounded pending inquiry.”

The order propagated while they watched. Nacre acknowledged first. Sable accepted four seconds later and requested authority to exceed the reserve increase if its inner cage moved. Brine's local controller asked whether the instruction applied during food-transfer traffic. Orison Gap reported insufficient coolant, then accepted after Charter logistics promised a tanker. Each acknowledgment added a hard blue ring around one point on Kessa's wake map.

She opened engineering projections for the commanded increase. At Nacre, two more percent would consume the thermal margin by the next pulse trough. Sable already ran beyond published output. Tern had taught the control system nothing because no cage remained there to receive the update.

“Your analysts can see those margins,” Kessa said.

“They see active routes carrying medical and evacuation traffic.”

“Those routes now sit on twelve loaded releases.”

“Your phrase assumes the conclusion.”

Kessa transmitted the raw Tern ratchet trace again, this time with each cut step removed. The hold corrections alone still climbed after the juvenile's physical response. “No cut in that segment. No collision. The cage adds energy each time the animal moves.”

Halvek glanced away. His staff had put another display beyond the camera, close enough for its pale reflections to cross his cheek. “A correlation under uncontrolled conditions.”

“You created the conditions.”

“I inherited a network carrying civilization.”

Around his face, the blue rings continued appearing. Ten anchors acknowledged. Eleven. The last delay came from Brine, where a local engineer had attached a request for worker review. Charter command overrode the request and marked the order accepted.

“You are tightening every restraint before the return.”

“I am preventing another uncontrolled breach.”

Kessa looked at the date on his order. Day 12. Thirty days remained if their

model held. Less if the cages had hidden more delay than Anu estimated.

"Marshal, Tomis ordered Lark-3 evacuated before the automatic hold overrode him."

For the first time, Halvek's gaze shifted to the brass key in her hand.

"You have the local trace beyond the corrected command extract?"

"I have forty-eight minutes. It shows the physical load arriving before any control action."

"Transmit those channels."

"After you suspend the reinforcement order."

"You are withholding safety evidence."

"I learned the procedure from you."

She ended the call.

Sena locked the cockpit hatch. "That exchange shortened our lawful future."

"Can we leave the berth?"

"The security grapple carries a bonded release. Our drives remain tagged. Berth control owns the outer doors."

Kessa inserted Tomis's torque key into the manual console's obsolete service slot. It did not fit by design. Brass edges caught on the newer collar.

She turned it anyway.

The key bridged two contacts. Manual maintenance authority opened for a half second, long enough for Sena to isolate the drive tags. Pell killed the tug's external network. Vasken released the security grapple by firing drum two against its hinge rather than its bonded latch.

An alarm spread through the berth.

Crew voices filled the ship channel. Some demanded an explanation. Others reported seals, pressure, and power. Kessa did not ask for loyalty while the outer door remained closed.

"Stations only," she told them. "Nobody has consented to a destination. We decide that after Sena gets us clear."

Berth control denied departure. Sena opened both grapple drums and caught the inner door rails. Threadbare pulled herself forward while the drums reeled, an eighty-three-metre tug climbing through an impound lock by her hands.

The door protested in red across every display.

Kessa reached the exterior release cabinet and used the torque key as a striker. The manual pins withdrew one at a time. Vacuum took the remaining pressure. The outer doors separated by two metres, four, then enough for Sena to turn the tug on edge and scrape through.

A security cutter moved to block them.

“Do not ram it,” Kessa said.

“I appreciate specific limits.” Sena rolled Threadbare beneath the cutter's exclusion cone and used the berth structure to hide their first burn. “Where?”

Twelve anchor points glowed on the manual console. Four lay within the tug's unassisted fuel reach. Every one carried a continuous hold.

Kessa fastened Tomis's key beside the controls, no longer closed around its hidden seam.

“Out of Nacre first,” she said. “Then we unfasten the chain.”

Threadbare cleared the evidence berth as its doors jammed behind them. Ahead, Nacre-9 tightened under nine reinforced beams, and the wake map counted thirty days toward something large enough to bend the Reach.

Act 2

Chapter 10 — A Ship Called Threadbare

Kessa crawled into Threadbare's port grapple drum while Sena kept the tug hidden behind Nacre's ore moon.

The stolen cage keys rode in a tool roll tied to her ankle. Nine ceramic wafers, each the size of a thumbnail, knocked together whenever she pulled herself through the narrow housing. Charter technicians used them to open resonator service locks without waiting for local control. Vasken had lifted the roll from the impound team during Tern decontamination and told no one until the evidence-berth alarm began.

Possession could cost every person aboard a route license. Use could bring prison.

The drum offered a more immediate problem. Its emergency release had bent when Sena tore the security grapple off Threadbare. One jaw remained half open. Unless Kessa reset it by hand, the tug had one working grapple for any cutting job ahead.

She wedged her shoulder beneath the guide plate and pushed.

Metal shifted by a finger-width. Pain drew a hot line across her left palm. The old resonator scar had opened under the glove liner at Tern and sealed badly. Kessa ignored it until blood made the guide slick.

"Chief," Pell called through the drum wall. "Crew count begins in twelve minutes."

"Call it a meeting."

"Sena calls it a consent muster."

"Sena enjoys words that prevent me from leaving."

"Thirteen minutes now."

Kessa braced both boots and forced the plate into its track. The jaw closed with a flat mechanical knock. No ghost load followed. No three-beat response moved through the tug. Behind the moon, Nacre-9 remained out of sight and held tighter than before.

She backed out of the drum with the cage keys still tied to her ankle.

All nineteen crew fit in Threadbare's centrifugal mess only by using the walls. The patched drum turned slowly to save power, giving them one third of standard gravity. Jori occupied a medical sling beside the galley hatch, his broken arm fixed across his chest. Anu stood near the repair-gallery door because she did not belong to the crew count and refused to pretend otherwise.

Sena had placed the ship covenant on the central table. Its display showed no

proposed destination.

Vasken noticed the tool roll first. "You brought the keys."

"I brought them to the people who would be charged for having them."

Pell looked around the crowded room. "Should we admire the distinction?"

"No." Kessa set the roll beside the covenant. "You should know exactly what we stole before anyone agrees to fly with it."

She listed the damage without reducing it to a speech. Both grapple drums worked, but port release required manual confirmation. Their cold-shear cutter had no lawful tool bond. Reactor output remained good. Fuel stood at sixty-eight percent after Tern and the impound escape. No Charter berth would service them. Nacre control had revoked water, repair, and docking access across the network.

Then she showed the wake map.

Twelve anchors curved across the mess display. Blue rings marked Halvek's reinforcement order. A moving field estimate approached the chain with thirty days remaining.

"Candidate adult veilback," Anu said from the wall. "Candidate matters. We have measured one large lens body through indirect effects. We have not observed it."

Kessa enlarged Tern's stored-gradient trace. "This part needs no candidate. A hold that opposes biological release accumulates stress. The cages are adding restraint at all twelve anchors."

Jori shifted in his sling. "And you plan to cut them."

"I plan to find out whether local crews carry the same load. If they do, I want to stop another Tern."

"That isn't an answer."

"No." Kessa looked at the sling around his arm. "I do not know how to release a juvenile safely. The cold-shear sequence failed under a hold. Anu thinks tissue response may show us another order, but she does not have enough data. We can inspect cages, share the Tern trace, and refuse any cut while a hold remains active."

A drive mechanic named Hara Senn folded her hands on the table. "Halvek says your cut caused the breach."

"My cut opposed his hold. I made it. He maintained his system after I stopped. Both actions entered the failure."

"Would you make the cut again?"

"Not the same one."

"Would you make any cut without Charter authority?"

Kessa considered the cage keys. "Yes, if the crew at that anchor requests it and we can remove the hold. Not before we understand more."

The room remained quiet enough for the drum bearings to carry through the deck. Kessa wanted to tell them that good hands could solve it. She wanted to turn uncertainty into a repair schedule and loyalty into a resource already aboard. Both desires came from the lie she had used since Tomis died.

Sena tapped the covenant. "This is not a majority vote that binds dissenters. Each person chooses whether to continue beyond Nacre's local volume. Anyone who declines keeps earned share and receives transfer on the neutral ore tender at the moon's far depot. It arrives in fifty-one minutes."

"The tender will report us," Vasken said.

"It already knows we're here."

Kessa looked at Sena. "You arranged a transfer before the meeting."

"I arranged a real choice."

That correction belonged among the expensive ones.

Pell opened the first consent line. "What are we consenting to? 'Unfasten the chain' has poor contract language."

Kessa entered terms one by one. They would carry Anu and the evidence to any route crew requesting inspection. They would not approach a cage under active Charter targeting if a worker aboard voted the approach unsafe. No one would be ordered outside for an unauthorized cut. Local crews controlled their own hardware. Threadbare would publish every measurement and keep no exclusive release method. Any crew member could withdraw at the next physical transfer point.

"And if there is no transfer point?" Hara asked.

"Then we use a shuttle, tug, or occupied station that accepts you. We do not leave anyone in a capsule to make the sentence true."

Jori lifted his good hand. "Medical authority says I cannot work exterior."

Anu said, "Medical authority sits here and says the same."

"Do I count as crew if I cannot do my berth?"

Kessa answered before anyone could make usefulness a condition. "Yes."

Sena added a line assigning Jori to internal load monitoring until cleared. "Consent does not require pretending you're uninjured."

The covenant circulated around the table.

Nobody signed quickly. Vasken read every clause twice. Hara asked whether the ship's debts would pass to families if Charter seized their accounts. Pell wanted raw evidence attached rather than summarized. Two junior riggers left the mess to call dependents through the ore tender's relay, then came back with faces Kessa did not try to interpret.

Anu signed as passenger and scientific authority, not crew.

Kessa waited last. Seventeen crew marks appeared. Sena's joined them. Jori

held the slate against his sling and entered the nineteenth with his off hand.

No one chose transfer.

The ore tender still came alongside. Its captain extended a personnel tube and waited because Sena had paid for the option. Kessa opened both hatches and left the passage lit for five full minutes.

Hara stood nearest it. Her partner worked a pressure plant on Nacre and had sent one message before Charter blocked the relay: Choose the ship only if they let you choose. Hara read the line to the mess without asking anyone to answer. Then she closed the tube's inner hatch herself.

One junior rigger, Deni Sol, kept his bag packed at his boots. "I signed for inspection," he said. "Not sabotage."

"So did I," Jori replied. "The difference may become inconvenient."

Kessa faced Deni. "If I order sabotage, invoke the unsafe-work clause and stop me."

"Against the chief and co-owner?"

"Against whoever gives the order."

Sena entered that sentence as an amendment to the covenant. Deni approved it and slid his bag beneath the bench, still packed.

The tender captain requested separation. Before Sena closed the outer lock, Kessa transferred a copy of the wake evidence and the crew's consent terms into its public mail queue. If Threadbare vanished, their departure would not become a Charter story about hostages or a chief fleeing discipline alone.

Mooring seals released. The personnel tube withdrew. Nineteen crew remained because each had passed an open hatch after seeing a route back.

The result did not feel like absolution. It felt like nineteen people placing their own names beside a risk Kessa could no longer call hers alone.

She signed the chief's line.

Sena closed the covenant and immediately opened the fuel plot. "Now for the part where consent meets range."

Twelve anchor points spread across the table. Sena drew four reachable arcs from their present fuel state. Nacre sat behind them. Lark-3 had no functioning corridor and no service mass. Brine lay three days away if they took a minor transfer route before Charter closed it. Orison Gap required refueling. Sable lay beyond two corridors they could not trust.

"With reserve for approach, failed grapple recovery, and leaving each cage," Sena said, "we can reach four of twelve."

Pell leaned over the plot. "Five if we stop heating the aft bunks."

"Four if we intend to arrive with crew."

"We own blankets."

"Your optimism consumes oxygen too."

Sena made them price each anchor in actual work. The nearest required a standard approach but no legal coupling, which meant Threadbare would spend fuel matching drift while Kessa opened the service lock manually. The second lay behind a corridor whose receiving cage had begun throwing clock errors. Reaching the third required a braking burn their port engine could perform once before replacing its throat liner. Brine consumed the smallest useful margin and placed them beside food traffic already threatened by closure.

Kessa opened the tool inventory. One cold-shear cutter remained aboard. Its thermal pack had survived Tern. The severed control bus had not. They owned two spare ceramic jaws, six metres of field braid, three isolation forks, and enough suit propellant for fourteen full exterior shifts if nobody needed rescue.

"That count assumes Jori stays inside," Hara said.

"It assumes every exterior pair carries reserve for a third suit," Kessa replied. "After Tern, we do not budget retrieval as an exception."

Vasken rolled the stolen cage keys across his palm. "Nine wafers. Twelve cages."

"Local crews should have their own."

"Local crews may have had them seized."

"Then we use one wafer per service system and preserve the serial records."

Pell brought up water. Impound had left their main tanks at seventy-one percent. The recycler's membrane carried a tear he had repaired with galley filter mesh. It would hold for days, not weeks.

"The ship can reach four anchors," he said. "The people can reach two unless somebody sells us water."

Anu looked toward the specimen bench. "The filament cultures require less than one person's ration."

"No one suggested dumping them," Pell said.

"You looked at their line."

"I look at every line that leaks."

Kessa separated scientific water from domestic load rather than letting the argument harden. The cultures might reveal why Nacre's tissue closed after cutting. They also occupied a resource every crewmember drank. Both facts belonged on the same slate.

By the end of the inventory, four reachable anchors had narrowed to one sensible first destination. Brine offered a requesting crew, local service access, food substrate, and enough habitat industry to trade for water or a throat liner. It also carried six point two million people around a cage Halvek had ordered reinforced.

Kessa moved fuel between scenarios. Abandoning the cold-shear cutter gained almost nothing. Its mass mattered less than the propellant needed to correct in unstable lens geometry. Trading spare radiator panels could buy fuel at a sympathetic station, if any station accepted them. No lawful berth meant no standard tank couplings, no certified water, and no repairs beyond what nineteen hands could perform aboard.

"The chain cannot be unfastened by one tug," Vasken said.

"No," Kessa replied.

"So what did we consent to?"

"Finding out whether other crews already know part of the answer."

She opened a draft broadcast.

Her first version contained Tern's casualty trace, the wake map, Tomis's Lark-3 log, and a demand that routekeepers reject Charter authority. It sounded decisive. It also asked workers to risk their stations and families on Kessa's conclusion before they could test it.

She deleted the demand.

The second version called the creatures juvenile veilbacks and described the approaching lens body. Anu removed both claims.

"You have evidence for juvenile tissue at Nacre," Kessa said.

"I have evidence for a regenerative filament associated with the hollow. We need local crews to inspect their own cages, not agree with my classification."

Sena crossed out migration chain. "You want answers from people who still think Tern came from your cutter."

"It came partly from my cutter."

"Then do not make them accept your innocence before they answer a gauge question."

Kessa stared at the empty message field. Repair work began with the condition nearest the hand. Not who owned the machine. Not what failure meant for civilization. First find the load.

She typed one question.

Does your cage carry the three-beat load?

Below it she attached a ten-second vibration trace from Nacre, the matching raw trace from Lark-3, and the Tern segment recorded before any cut began. Anu added instructions for separating physical strain from control traffic. Sena included an address that bounced through old union maintenance relays rather than Charter routing.

Pell read the message. "No accusation."

"No."

"No plan."

"Not until we have one."

"No stirring statement about roads built on bodies."

Kessa looked at him.

"I can write one if morale requires it," he said.

"Repair the water recycler."

"Cruel but lawful under the covenant."

They sent the broadcast from behind the ore moon.

Nacre security found them four minutes later. Two cutters cleared the moon's northern limb on intercept burns. Their weapons remained cold, but targeting cones spread across Threadbare's escape path.

Sena had predicted the approach. She rolled the tug close to the ore tender's thermal wake, then burned toward the minor transfer corridor with the tender between them and direct fire.

The tender captain called in outrage. "You said no fighting near my hull."

"We are not fighting," Sena said.

"The Charter cutters look emotionally prepared."

Kessa opened the cutter channel. "Nineteen crew and one civilian scientist aboard. We are under independent ship covenant. Any grapple attempt near the tender risks collision."

"Cut thrust and surrender stolen Charter property."

Kessa put the ceramic cage keys on camera. "These open worker service locks. If you want to argue ownership, begin with the workers."

The lead cutter accelerated.

Sena fired Threadbare's starboard grapple into the ore tender's discarded slag mass, reeled hard, and swung the tug around it. The cutter followed the expected thrust line. Threadbare crossed beneath its cone and released the slag. For several seconds the cutters had to choose between pursuit and avoiding fifty tonnes of molten tailings.

They chose their radiators.

The minor corridor opened ahead as a thin lens between two utility anchors. Its control system denied Threadbare authorization. Kessa inserted one stolen cage key into the manual reader.

SERVICE ACCESS recognized the wafer. The throat widened enough for one tug.

"Using it records the serial," Vasken said from load control.

"They know our name."

"I meant the worker who loses it."

Kessa hesitated. The wafer carried a local issue code from Nacre. Someone on the cage crew had signed for it.

She copied the access log, added her own authorization, and transmitted the record publicly before crossing. Theft remained theft, but she would not let Charter place the consequence on an unnamed worker.

Threadbare entered the corridor.

Stars drew into paired arcs around the cupola. The drum bearings changed pitch. Every crew station reported manual readiness. No fixed-route passage had ever felt so much like a door they might not deserve to use.

Kessa kept her hand near the drive cut until ordinary stars returned on the far side.

The first answer waited in their maintenance relay.

A routekeeper at Glass Minor had laid a palm sensor on an outer feed and recorded three measured impacts. The crew attached raw clocks and no interpretation. A second report came from a decommissioning team near Sable. Their cage carried the load beneath continuous hold, strongest after each Charter correction.

More answers arrived as Threadbare moved into ordinary flight.

One crew accused Kessa of manufacturing the trace and still sent its data for comparison. Another had heard three knocks through a thermal conduit for six months. A fifth reported branching frost at two resonators. The sixth local crew offered complete unaveraged station records under the condition that no names appear until their families left Charter housing.

Anu built each trace into the wake map. All six matched the physical sequence within their instrument limits.

None offered a safe cut.

Kessa had not asked for one.

A seventh packet arrived from Brine. Condensation blurred the sender's camera. Behind the routekeeper, green algae light reflected from a habitat transfer spine. The local cage trace showed three beats, a pause, then a hold correction strong enough to drive the outer feeds past thermal margin.

The routekeeper looked directly into the lens.

"We carry it," she said. "Food traffic has us locked under continuous hold, and the juvenile is moving. If Threadbare can cut without making another Tern, come to Brine."

The packet ended with approach data and a local service key.

Sena laid in the three-day burn. Fuel reserve dropped across the plot, leaving the other eight anchors beyond anything one tug could reach.

Kessa touched the open seam in Tomis's torque key. Six crews had given them

data. Brine had given them a place where delay already had a temperature.

“Accept the approach,” she said.

Threadbare turned toward Brine with nineteen crew aboard, no lawful berth behind her, and a question traveling faster than the ship could follow.

Chapter 11 — Brine Habitat

Condensation struck Accord of Dust's docking collar hard enough to sound like rain.

Irian listened from the transfer control bay while Brine's outer cylinder rolled past the port. Green algae lamps shone through wet glass. Agricultural drums occupied every orbit around the red dwarf, dozens of long habitats threaded together by transfer spines and cargo loops. Their cooling skins shed water vapor into capture nets. From a distance the swarm had looked lush. Up close, every surface carried patched seals, mineral streaks, and painted capacity marks.

Brine grew food for systems that referred to it as substrate capacity.

Its docking controller denied Accord's first cargo request.

"Priority evacuation convoy," Irian said. "Fourteen mobile kitchens reach reserve limit in thirty-one hours. We require sixteen thousand tonnes of food substrate, water concentrate, and nutrient cultures."

A Brine coordinator appeared on the bay display. Lio Varen had silver hair cut to the scalp and condensation beaded across his collar. The room behind him contained algae pipes rather than a command table.

"We received your requirement," he said.

"Then open freight access."

"No."

Irian checked the channel header in case some negotiation layer had failed. "Brine holds a Charter emergency reserve sized for three convoy transits."

"It held that reserve before the anchor began moving."

"We carry four hundred ten thousand evacuees."

"Brine houses six point two million people."

The answer entered the bay like a shifted load. Irian had not forgotten Brine's population. She had placed it in a separate column: local demand, protected by local stores. Her convoy occupied the urgent column because it moved and consumed reserve without replacement.

Varen sent a transfer schedule. "We will distribute food substrate when your convoy accepts thirty-eight thousand Brine residents and moves six vulnerable cylinders out of the anchor plane."

Irian enlarged the list. Dialysis wards. Two old residential drums with failing radiation shells. A school cylinder whose drive collars had been removed for parts. Twelve thousand agricultural workers housed along the transfer spines nearest the cage.

"You are conditioning emergency food on transport," she said.

"We are conditioning exported food on shared evacuation."

"Those cylinders cannot attach to Accord without load review."

"Then review them."

"My convoy remains split. One third has no fixed corridor. We lost fuel recovering a hospital at Tern. Halvek offers a departure sequence in eighteen hours if Brine releases our cargo now."

Varen wiped moisture from his jaw. "Your departure sequence crosses our anchor while our least mobile residents remain beside it."

"We cannot absorb every threatened habitat along the route."

"No. You can absorb the people whose food you want."

The channel ended without a docking assignment.

Irian stood over the dark display until Marl Quade entered the bay. He wore Brine condensation on his shoulders and carried a paper band around one wrist, local access issued without connection to the Charter network.

"You went ashore without clearance," she said.

"I went through a tube they opened."

"They refused our freight request."

"They refused your supply-stop request."

Irian turned toward him. "Our kitchens have thirty-one hours."

"Brine's outer spines may have days."

"We cannot plan a mass carrier around every local demand."

Marl set a wet glove on the console. "You called this habitat a supply stop before we docked. People here heard you. They spend their lives sending food into route schedules written elsewhere. Now the routes are breaking, and the first emergency fleet to arrive asks them to load our holds and remain under the cage."

"Their reserve exists for transit failures."

"They have one."

Irian looked through the port. A transfer spine passed beneath Accord's collar, crowded with handcarts and people in green work coats. Condensation made the outer windows opaque in patches. Beyond them, Brine's anchor bent the red dwarf into a dark-edged crescent.

"Thirty-eight thousand residents alter life support, berth, and fuel."

"So does food substrate."

"You think I should accept the condition."

"I think you should stop treating their people as an unexpected surcharge on cargo already owed to us."

Marl rarely raised his voice. He did not now. That made the correction harder to

classify as anger and easier to recognize as accurate.

Irian reopened Varen's schedule. "Six vulnerable cylinders cannot all ride Accord's truss."

"Brine knows that."

"Then why ask?"

"To find out whether a convoy means one carrier or many ships."

The phrase touched the same defect Tern had exposed. Irian could move mass through a planned route. She could not pull every module herself once geometry failed. Manual slates had kept the hospital alive because many ships reported what they saw. Brine wanted the same distribution applied to people.

"Convene passenger delegates," she said.

Marl did not move. "For what question?"

"Taking Brine residents aboard and changing departure."

"Under which authority?"

"Emergency convoy command."

"That gives you rescue authority for immediate life threat. Destination changes require the Free Convoy Articles."

Irian knew the Articles. She had signed them at departure because no civilian convoy of this size could sail on naval precedent alone. Captains retained ship safety. Passenger delegates held consent over uncharted mass movement, abandonment of inhabited modules, and destination changes beyond published emergency ports.

Brine appeared on the published route as a supply stop, not a destination.

"We are not choosing a final destination," she said.

"We are choosing whether thousands board ships that expected to leave in eighteen hours."

"The anchor may fail before a full delegate session finishes."

"Then give them a deadline and the information."

Irian disliked procedures that consumed the margin needed to carry them out. She disliked unilateral command more when someone forced her to name it.

"Two-hour session," she said. "Ship captains and passenger delegates. Brine sends representatives. Raw capacity tables stay open."

Marl removed his glove from the console. A wet handprint remained. "Now you have a question."

The assembly met across eleven linked rooms because Accord had no chamber large enough for every delegate. Faces occupied the logistics pit wall in a grid. Captains joined from bridges. Passenger delegates spoke from habitat messes, clinic bays, machine shops, and one agricultural drum where people stood

ankle-deep in loose soil after Tern's burn.

Lio Varen appeared from the algae-pipe room.

Irian presented capacity first. The main convoy segment could take thirty-eight thousand people if it converted freight berths, doubled six habitat occupancy limits, and moved water bladders outside pressure. Six Brine cylinders required eighteen tugs. Eleven were available without stripping tow from weak convoy habitats. The remaining seven could come from Brine if local crews accepted fuel support later.

Then she presented cost. Taking the cylinders delayed departure by at least thirty-six hours. Halvek's timetable closed in eighteen. Missing it removed the Charter guarantee of two stabilized corridors toward Orison staging. Fuel after the hospital rescue allowed no rapid alternative.

A delegate from Kindly Argument asked, "What does Charter guarantee mean after Tern?"

"Halvek commits cutters, route clearance, and reserved transit order," Irian said. "He cannot guarantee cage geometry."

"Can anyone?"

"No."

A freight captain leaned close to his camera. "We carry machine seed for three systems. If we take local residents, their cylinders displace protected cargo."

Varen answered, "If you leave without substrate, your seed arrives with hungry operators."

"That reserve belongs under intersystem emergency compact."

"It belongs in Brine tanks maintained by Brine workers."

Marl called the next speaker before ownership could consume the question.

A passenger delegate from Cylinder D-19 held up a manual navigation slate. "At Tern, a borrowed tug kept our air processors aligned. We should lend tow here. But destination cannot follow every rescue request. Where do we stop?"

Irian could have answered with capacity. Instead she gave the boundary. "We stop where accepting more people makes survival less likely for those already aboard. Brine's request does not cross that line if we distribute load. It does erase schedule and fuel margin."

"How much survival margin?"

"For food, it improves. For water, it holds if Brine transfers concentrate. For berth pressure, we fall to twelve percent spare. For fuel, we lose Halvek's sequence and take an unreserved approach toward Orison."

Another delegate asked whether Accord could carry the food and leave the six cylinders for local tugs.

Varen's face hardened. "Our condition includes the cylinders."

“Why those six?”

“Because every evacuation plan written before yours moved working adults first. Those cylinders contain people who cannot cross transfer spines quickly. If we let the strongest board your ships and call that rescue, the route fails around everyone else.”

The school cylinder's delegate appeared beside him, a young instructor with algae stains on both sleeves. She turned her camera toward a corridor lined with folded sleep pallets. Children sat strapped into travel webbing, each wearing a paper band like Marl's.

“We can supply two tugs,” she said. “We need four. Our drive collar has not moved the cylinder in nine years.”

No one on the assembly spoke for several seconds.

Irian refused the easy use of the image. “How many aboard?”

“Five thousand eight hundred twelve. Eleven hundred children.”

“Pressure endurance detached from Brine?”

“Eighty days with water resupply. Forty-three without.”

“Spin collar?”

“Functional at present mass.”

“Bring your maintenance file into the common stack.”

The instructor did. Work replaced spectacle.

Over the next hour, captains broke the six cylinders into tow problems. Two could pair behind a water barge. One residential drum needed bearing service before any translation. The dialysis wards could divide between Kindly Argument and three clinic modules if their patients consented, reducing tow mass. Brine crews offered seven local tugs but lacked fuel for the full approach.

Irian moved resources while everyone watched.

She had spent years protecting reserves by keeping them concentrated where trained crews could account for them. Tern had turned that efficiency into a target. One closing lens nearly took the hospital and its pharmacy together. One corridor breach had separated convoy kitchens from food barges.

“No single ship carries a survival monopoly after Brine,” she said.

Load control opened the distribution board.

Food substrate would go to twenty-four ships, not only Accord's central kitchens. Water concentrate would divide among sixteen mobile tanks and six habitat reservoirs. Machine seed, packaged as fabrication cultures and tool-pattern cores, would leave the protected freight spine and travel in twelve sealed lots. Every weak habitat received seven days of independent food. Every tug cluster carried enough water to survive separation from the carrier.

A cargo officer objected. “Breaking machine seed lots voids contamination

certification.”

“Keep original seals and split by complete culture family.”

“We cannot duplicate every pattern core.”

“Then distribute overlapping sets. No one ship receives all of anything we need to live.”

A passenger delegate from the recovered hospital raised her hand. “Test it.”

Irian looked up from the board. “Specify the loss.”

“Remove Accord.”

Several bridge officers objected at once. The carrier provided central water treatment, machine shops, navigation staff, and most of the convoy's protected storage. Planning for its loss during a supply transfer sounded like inviting panic.

Irian blanked the eleven-kilometre truss from the distribution model.

Red shortages spread across thirteen ship groups. Three habitats had food but no nutrient starter for their kitchens. A tug cluster carried water concentrate without a membrane capable of processing it. Five machine-seed lots overlapped in pattern cores yet all depended on one calibration culture still assigned to Accord.

“There,” the delegate said. “You distributed containers. Not use.”

Load control began repairing the design. Brine offered compact membrane racks from two agricultural drums. Kindly Argument could carry three calibration cultures in separate sterile wards. Captains moved starter stock into habitat kitchens rather than leaving it aboard freight tenders. Every change cost berth space and handling time.

Marl asked for a second test. “Remove Brine's largest substrate carrier.”

The model lost eleven days of food from the outer convoy group. Irian split its cargo among four smaller ships, including one whose captain had refused evacuation passengers. The captain accepted common reserve cargo under the Articles while retaining his refusal on berths. Consent did not require every choice to point the same way.

A third simulation stranded the water barges. A fourth removed Kindly Argument. Each failure found a dependency they had mistaken for distribution. By the fifth run, no single ship loss starved the convoy. Some combinations still did. Irian published those combinations rather than sanding uncertainty from the board.

“This increases transfer time by six hours,” her cargo officer said.

“It buys survival after separation.”

“It also guarantees we miss Halvek's sequence.”

Irian watched Brine's six vulnerable cylinders on the adjacent plot. The schedule had already become a cost, not a plan she could keep by refusing to name the

exchange.

Marl looked at the board. "Including authority?"

"That question belongs to the Articles, not my load office."

"It belongs here too."

Irian let the comment remain.

The redistribution created work across the convoy. Cargo crews had to open holds designed for arrival at distant ports. Habitat delegates had to choose storage rooms, displacing beds and workshops. Brine workers would fill unfamiliar couplings under time pressure. None of it matched the clean transfer promised by Halvek's schedule.

A captain from a seed barge asked who carried loss if a distributed lot spoiled.

"All of us," Irian said. "We publish each location. Any ship that loses refrigeration announces immediately, and the nearest overlapping lot replaces it."

"That makes private cargo common reserve."

"During separation, yes. Ownership claims survive. Hunger does not wait for adjudication."

The captain requested the statement entered verbatim. Irian entered it herself.

At the two-hour mark, the assembly had not reached unanimity. The Articles did not require it for accepting passengers. They required recorded consent from each affected captain and passenger delegation, plus a right to refuse a destination change that exceeded their ship's safety margin.

Three freight captains refused Brine cylinders. Two passenger groups declined extra occupancy because their air systems lacked reserve. Irian accepted those refusals and reassigned no tug from them. The remaining ships produced enough berths and tow to carry the request.

The vote passed by ship group, not by head count. Each approval included capacity conditions anyone could inspect.

Varen reopened the freight valves.

Food substrate began moving through Brine's crowded transfer spines in warm green tanks. Water concentrate followed in silver bladders. Along a parallel line, the first residential cylinder detached from its damp berth under four tugs. Condensation broke from its hull in a glittering sheet.

Irian went down to the transfer spine rather than watch icons.

Heat pressed through her uniform. The corridor smelled of algae, wet metal, and too many bodies waiting beside packed bags. Brine residents had marked cargo lanes with green tape. Convoy crew rolled empty substrate tanks inward while local workers pushed personal cases outward. Neither flow yielded naturally to the other.

Marl walked beside her. "Still look like a supply stop?"

"It looks like a collision between two manifests."

"That is almost progress."

At the school-cylinder junction, children waited in paired lines with paper bands around their wrists. Each band named a destination ship, responsible delegate, water assignment, and reunification point. Adults checked the marks by hand because Charter identity routing had become unreliable.

Irian stopped beside a girl whose band listed Accord, Drum Twelve. "Who gave you that berth?"

The girl pointed to a Brine clerk.

Irian asked the clerk for the matching load entry. He found it in the common stack. Drum Twelve had capacity and an assigned school group. The paper band agreed with the convoy file.

One checked child could not prove a system. It could show whether the system reached a hand.

Her wrist display lit with Halvek's call.

He did not waste time. "My reserved sequence begins in thirteen hours. Route control cannot hold the slots beyond that."

"We need at least twenty-seven."

"Then detach the Brine cargo and depart with your original convoy."

"The cargo includes residents under accepted Articles."

"You are risking four hundred ten thousand people for a local evacuation Brine had years to plan."

"Planning did not give their cylinders drives."

"Your duty does not expand with every need you encounter."

"No. It expands when I take the food that lets my people survive."

Halvek sent the revised route table. Two corridors showed reserved green. After thirteen hours, both became unassigned traffic under reinforced hold. Irian understood the value he offered. Cutters would clear approach. Fuel tenders would wait at Orison staging. The schedule could pull her scattered convoy back toward one plan.

It also required leaving while Brine's vulnerable cylinders remained beside a moving anchor.

"Commodore," Halvek said, "Tern proved the cost of improvisation."

"Tern proved the cost of calling one system safety while it pulled against another."

"This is logistics, not your routebreaker's biology."

"Logistics includes who gets left under the machine."

She declined the reserved sequence.

The green corridors vanished from her display. Fuel tenders, cutter escort, and guaranteed transit order disappeared with them. Her navigation staff would have to build an approach from direct sightings, local tugs, and whatever geometry survived the delay.

Irian entered a new convoy commitment under the Free Convoy Articles: complete Brine's agreed evacuation, distribute survival stores, then depart by ship-specific readiness rather than one centralized slot.

Marl read it before signing as delegate witness. Lio Varen added Brine's obligations: substrate, water concentrate, seven tugs, repair access, and resident manifests. Captains began attaching their accepted loads.

Outside the spine windows, Threadbare crossed toward Brine's anchor, small beside the nine resonators and the dark they held. Six local routekeeper teams moved around the cage with instruments on their suit rails. The next three-beat pulse had not yet arrived, but every Brine transfer schedule now ended with a margin for it.

The school cylinder pulled free under four tugs.

Its wet hull carried five thousand eight hundred twelve people away from the anchor plane. Food tanks moved the opposite direction into Irian's scattered convoy. Nothing followed Halvek's timetable now.

Irian watched both flows cross without colliding and committed the rest of her ships to the same difficult exchange.

Chapter 12 — The Anchor Choir

Kessa tightened the recorder clamp until the old transfer spine complained through her boots.

Brine's anchor hung beyond the cylinder swarm, nine resonator stations arranged around a patch of dark that refused every honest outline. Condensation from the habitat locks had frozen across the spine in cloudy scales. Each time the structure shifted under traffic, frost snapped free and drifted toward the red star. Six routekeeper craft held position at measured intervals outside the cage. Their work lights gave the dark center six different edges.

"Clamp is carrying," Kessa said.

Anu floated beside the recorder rack with one knee hooked through a handhold. "It carries your mass. That does not make it quiet."

"Nothing here is quiet."

The three-beat load had crossed their hull twice since Threadbare matched Brine's anchor drift. Kessa felt it now through the spine: pressure, release, pressure, release, pressure, release. A cutter captain from Gannet had called it a knock. The Hush team called it a harmonic. One Brine technician had submitted possible intentional transmission in a preliminary log and started an argument that consumed forty minutes they did not have.

Kessa attached a second brace to the rack. "Run it."

Anu opened the six-team feed. Lines climbed across the portable screens. Each recorder caught cage strain, local gradient, filament conductivity, resonator output, and the motion of reference lights placed beyond the anchor. Six clocks had been uncoupled from Charter timing. Six crews watched one physical event without letting a central system decide when it happened.

The first beat reached Gannet's frame.

A fraction of a second later, the Brine spine flexed beneath Kessa. The load crossed Threadbare, passed through the dark center, and touched the Hush recorder last. Its order matched position. Nothing in the station network routed it.

"Mark peak interval," Anu said.

Voices answered from the six craft.

"Gannet has point-eight."

"Hush has point-nine-four."

"Mica Hand, one-point-one and falling."

"Brine local, filament lag increasing."

Two other teams reported numbers. Nobody called the pattern a message this time.

Kessa watched the traces settle. The peaks carried the same three-beat shape they had recorded at Nacre, Tern, and along the twelve-anchor wake map. Their spacing had changed. The second pressure rise arrived early. The third dragged across a shallow series of tremors that set the recorder teeth chattering.

Anu enlarged the troughs. "Stress response."

"From traffic?" asked Orra Senn aboard Mica Hand.

"From restraint. Traffic adds a smaller modulation at the corridor mouth." Anu tagged two bands in different colors. "The timing shift follows resonator load. If this were language, the cage would be composing most of the sentence."

A routekeeper on Gannet said, "You can't rule out encoded content from six samples."

"I can rule out your preferred translation."

"My preferred translation is that I don't lose my license over animal weather."

Anu's mouth tightened. "It is not weather. It is also not language. Those categories do not exhaust nature."

Kessa pushed away from the recorder and crossed the spine toward the manual cage board. Brine had built its control platform for technicians in pressure suits, with broad keys and mechanical covers over the dangerous commands. A Charter lock icon glowed above every resonator channel. Local crews could trim power. Full release required authority that had already left Brine aboard a cruiser.

Below them, habitat cylinders crowded the transfer lanes. Passenger ferries moved families from damp homes to convoy berths. Cargo pods followed with algae stock and food substrate. The evacuation had turned every schedule into a negotiation between bodies and tanks. One spine carried outbound traffic from three cylinders because another had jammed under an overloaded coupling. If Brine's corridor failed violently, six million people would not fit anywhere else.

If every hold remained, the returning adult would find twelve injured juveniles pinned across its path.

Kessa opened the routekeeper channel. "We test a partial release. Outer three stations only. No cutting. We watch contraction and stop."

Gannet's captain answered first. "Charter denied that sequence."

"Charter denied everything except reinforcement."

"Reinforcement keeps the corridor stable."

"For how long?"

Nobody supplied a duration.

Orra sent her vessel's local authorization key. "Mica Hand consents."

Brine local followed. Then Hush. The other teams waited while Kessa studied the cage diagram. Outer stations Two, Five, and Eight sat at the widest load nodes, each separated from the next by two working resonators. Shutting them together

would loosen the cage without dropping a continuous side. At Tern, the safety hold had fought Kessa's cold-shear sequence and stored the mismatch until the spindle broke. Here, no blade would touch filament. No inner field would move.

Anu pulled herself to the board. "The juvenile may contract. It may expand. It may rotate its topology out of our measurement plane. None of those responses grants permission to infer preference."

"Can any kill the transfer spine?"

"Expansion could change local gradients beyond our present margin."

"How far beyond?"

"Ask after we measure it."

Kessa gave her a flat look.

Anu glanced toward the ferries. "My conservative estimate keeps the spine inside tolerance if we cut outer power by twelve percent per minute. My confidence does not deserve the word conservative."

That sounded more useful than certainty.

Before authorizing the ramp, Kessa made every team prove its stop path. She called stations in physical order rather than by ship name. Gannet showed a hand on its local breaker. Brine's pair pulled the sealed cover from a mechanical interrupt nobody had tested since the last cage overhaul. Hush discovered that its command still passed through a Charter timing filter and rerouted the lead through an inspection socket.

The work consumed four minutes of their traffic window. It also exposed three different meanings of manual. On Mica Hand, Orra's breaker separated the control beam from its power amplifier. Gannet's switch merely requested separation from a processor. The Brine interrupt dropped the whole outer station into passive cooling, after which restoring it would take forty minutes and a fresh alignment crew.

"Then Brine owns the honest switch," Kessa said.

Gannet's captain muttered something about obsolete equipment.

"Obsolete equipment can still fail without asking permission."

Vasken came across from Threadbare with two portable load cells. He fixed one above Kessa's boots and crawled to place the second past the nearest spine joint. The cells would tell them whether a gradient change crossed the structure or pulled the whole segment at once. Kessa checked both attachments herself. A sensor clamped to frost measured optimism.

While she worked, a ferry eased from the lower lock with Brine families visible through its small ports. Bags filled the aisle behind them. One child had pressed both hands to the glass to watch the routekeeper craft. The ferry pilot asked whether to hold departure until the test ended.

Kessa read the traffic plot. Keeping a loaded vessel beside the spine created one danger. Sending it through an altered corridor created another.

"Clear the local plane and wait outside cage control," she said. "You leave after we restore the published geometry or establish a new one."

The pilot accepted without asking which outcome Kessa expected. Below the platform, the ferry drifted to a marked refuge box. Its presence put people inside every margin on her slate.

Kessa transmitted the ramp to all six teams. "Any recorder loses independent timing, call stop. Any reference light departs its box, call stop. No one completes the shutdown on remote instruction."

The Gannet captain swore softly, then sent consent. The last two teams followed.

Sena spoke from Threadbare's cupola. "Traffic window closes in eleven minutes. After that, a loaded ferry crosses the near plane."

"We'll finish in eight."

"You said that about replacing my port manifold."

"The manifold lacked biological cooperation."

"Still does."

Dry laughter moved across two channels. It ended when Kessa lifted the cover over Resonator Two.

She pressed the manual trim.

Power fell by twelve percent.

The anchor's star arcs widened. Frost lifted from the spine in a sheet and hung without choosing a direction. Kessa felt no pulse through her boots. The juvenile's bent-dark outline remained broad and low beneath the corridor mouth.

"Two stable," Brine local reported.

"Gradient lag point-three seconds," Anu said. "Continue."

Kessa lowered Two through four more increments. At sixty percent, something moved behind the lens distortion. A pale branching trace appeared where no surface should have caught light. Filaments drew inward from the outer node, not as a recoil from failing power but as a coordinated contraction around the denser center.

The three-beat pulse came again.

Its first rise struck softer. The second held longer. The third ended without the ragged tremors.

Every recorder captured the change.

"What does that mean?" Gannet asked.

"Less strain," Anu said.

"You said no translation."

"Less strain is measurement. 'Thank you' would be translation."

Kessa closed Resonator Two completely. No alarm sounded. The corridor narrowed by two percent, still wide enough for the scheduled empty cargo pods. She moved to Five.

Under the second ramp, the juvenile shifted away from the disabled station and distributed its topology across the remaining field. Kessa knew that motion. Any suspended load sought a path. A living load also protected damaged structure, thickening one filament web while another loosened. The distinction showed in sequence rather than intention.

"Reference light Seven drifting," Hush called.

Kessa stopped the ramp.

Sena overlaid the external track. "Seven is inside its box. Recorder compensation misread the red-star flare."

"Hush confirms. Continue."

Five stepped downward. The pulse crossed again before the station reached zero. This variation carried a shorter interval between first and second beats, followed by a clean trough. Anu marked the timing against local field strength. Her screen filled with converging slopes.

"We're changing the relay delay," she said.

"Relay?" Orra asked.

"Biological propagation. The load passes through filament architecture, not empty geometry. Reduce restraint and conduction changes."

Gannet's captain said, "Across how many anchors?"

"Twelve measured. Possibly more."

"And every one feels what we do here?"

Anu looked at Kessa before answering. "Not what we do. A migration state passes along the chain. Local injury changes its timing. The next juvenile receives that altered state through the shared gradient."

The channel stayed silent long enough for Kessa to hear Brine's coolant pumps through the spine.

People wanted a voice because voices could agree, accuse, or forgive. A bodily chain allowed none of those comforts. It carried condition. One trapped animal tightened against a cage. Another responded to the changed rhythm because its life cycle had shaped it to do so. Humans had inserted machinery into that loop and mistaken the resulting stability for ownership.

Kessa moved to Resonator Eight.

A priority signal overrode the work channel before she touched the trim. Halvek's image appeared on the cage board, compressed by relay delay but

unmistakable in his dark Charter uniform.

“Routebreaker Rho, cease unauthorized manipulation of Brine Anchor Three.”

Kessa left the station cover open. “Local routekeepers have accepted the test under worker-stop authority.”

“Worker-stop authority permits suspension. It does not permit modification.”

“Two outer resonators are down. Corridor geometry remains inside traffic tolerance.”

“That condition will be reversed.”

“Not through this board.”

Halvek glanced offscreen, reading data from analysts she could not see. “Brine carries famine substrate for three systems. Your experiment narrows its only outbound corridor during an active evacuation.”

“Your hold injured the animal at Tern and killed sixty-three people.”

“The failed cut killed them.”

“Your beam fought the cut.”

“And your present action risks repeating the failure on an inhabited station.” His voice held no heat. Capacity moved through every syllable. “Restore Two and Five. Stand clear of Eight. I will not trade six million lives for a hypothesis.”

Anu entered the pickup. “The stress reduction is measured. We have six independent records.”

“You have eighteen minutes of data.”

“We have a response across the chain.”

“Then send it for review.”

Kessa saw the remote-control icon change before Halvek finished. A second authorization wrapped around each resonator channel. Continuity had reached the network through a relay outside Brine's local lock.

“Orra,” Kessa said, “cut Charter reception.”

“Trying.”

The icon turned red.

Resonator Two ignited at full hold strength.

The spine kicked sideways.

Kessa struck the board with her shoulder. Her tether caught, wrenching her across the rail as the stars beyond Brine folded into sharp pairs. Five came online half a second later. The juvenile had contracted around reduced pressure. Restoring both fields without a ramp trapped that contraction and forced its topology outward through the remaining nodes.

“Hold override!” Brine local shouted.

“Eight is climbing on its own.”

Anu clung to the recorder rack. Every filament trace on her display surged. “Kill the inner six. It needs somewhere to contract.”

Kessa reached for the emergency bank. Charter locks covered those controls too.

A sound traveled through the transfer spine, too low for the suit microphones and strong enough to move her teeth. It came without words or intention. Metal took the load because the juvenile's changing field had nowhere else to go.

Below them, a passenger ferry rolled hard against its docking collar.

Sena fired Threadbare's grapples. One line caught the ferry's forward tow lug. The other struck the spine beyond Kessa and locked. “I have the near segment. Far segment is opening.”

Kessa looked down the spine. Two hundred metres away, a joint ring stretched into an oval. Its bolts did not snap together. They failed around the circumference in a running pattern, each bright fracture chasing the next. Beyond the joint, three ferry locks and a crowded staging tube began to drift.

“Evacuate far segment,” she called. “All locks release ships. People in the tube move inward now.”

Brine controllers took over the order. Ferries fired side thrusters inside margins meant for docking. One scraped a radiator bank and spun clear. The staging tube's emergency shutters began closing, slow against the changing geometry.

The three-beat pulse struck through Kessa's tether.

Its intervals had collapsed. The third beat broke into rapid trembling before falling away.

Anu shouted over the alarms. “That is acute stress. Not speech. Record it.”

The demand sounded brutal until Kessa understood. If they lost the spine and saved only people, Halvek could rename the event. The cage would report a control fault. Charter timing would smooth the pulses. Every independent recorder needed to survive.

“Hush, take the raw feed. Gannet, mirror Hush. Mica Hand, publish while we still have relay.”

Orra answered, “Already moving.”

Kessa pulled herself toward the stretched joint. She could not repair a load path while space changed around it. She could, however, choose what failed first. The staging tube carried ninety-two people according to the lock count. Its support cables crossed the joint beside coolant and power trunks. If those trunks tore before the shutters sealed, decompression would vent both segments.

“Vasken, exterior team to my position. Cold cutters.”

Threadbare's riggers came out through the tug's dorsal lock. Sena held the near

spine with both grapples while Brine tugs caught the drifting far section. Between them, the joint continued to open.

Kessa braced her boots and cut the first power trunk. The severed ends flashed inside their shields. Vasken took coolant. Another rigger severed data bundles one bank at a time. Each removed connection reduced the chance that the separating spine would unzip a pressure wall.

"Shutters sealed," Brine control reported. "Far staging holds pressure. All passenger craft away."

"People in the tube?"

"Sealed with it. Rescue berth coming."

The final structural web stretched white.

Kessa cut it.

The far spine moved twelve metres in one breath. Brine tugs arrested the drift. No air burst from the staging tube. Threadbare's grapple drums groaned but held the near section away from the anchor plane.

Behind Kessa, every outer resonator burned at forced output.

Halvek's image had vanished from the damaged board. His command remained in the cage.

Anu crawled across the rail, one arm held against her ribs. "The contraction reversed. Filament stress exceeds the Tern baseline."

"Can we stop the hold?"

"Not locally."

Kessa stared at the red control icons. A machine hundreds of thousands of kilometres away had reached into Brine and closed a fist around an animal already learning to loosen itself. Halvek would say he had preserved the corridor. The corridor still shone black between bent stars. Beneath it, the juvenile's topology pressed hard enough to tear inhabited metal apart.

Orra reopened the six-team channel. More voices entered than before. Routekeepers from Nacre, Hush, Gannet, Lark, and four stations Kessa knew only by call sign had copied the published feed. Tool microphones carried three measured loads from one cage to the next. Each arrival showed a related timing change. None carried a word.

Gannet's captain spoke first. "My crew has it through a torque frame."

A Nacre worker answered, "We have the same trough collapse."

"Lark local confirms three-beat arrival. Charter monitor labels it stochastic cage noise."

Brine's far staging tube reached a rescue berth. Ninety-two pressure-suit beacons moved across the connector, one after another. Kessa counted until the last cleared.

Anu sent the comparative trace into the open channel. "The variations follow injury and release timing. Do not assign vocabulary. Do not answer it. Record load, interval, and field state."

Someone from an unnamed anchor asked, "What do we call it in the maintenance log?"

Kessa looked past the broken spine at the six craft holding their places around Brine's dark center. Across the Reach, workers had palms on torque frames, grapple lines, station rails, and old manual boards. The pulse moved through their tools because it moved through the bodies human machinery restrained.

Orra said, "Call it biological propagation."

Gannet's captain released a rough breath. "Charter will reject that."

"Then let them reject all six clocks."

Another routekeeper came onto the channel. "Hush station refuses noise classification."

"Nacre refuses."

"Lark refuses."

Names followed, scattered across the chain. Nobody offered a translation. Nobody claimed the juvenile had asked for help. They stated what their instruments carried and what the timing did under pain.

Kessa put one glove against the recorder clamp she had tightened before the test. Three beats passed into her palm, uneven now but distinct.

Around Brine, routekeepers opened their local logs and entered the pulse under load.

Chapter 13 — Halvek's Arithmetic

Halvek moved the seventh convoy marker out of the red column and watched two medical systems turn black.

The operations table aboard Continuity displayed the Lumen Reach as capacities rather than stars. Green threads showed open anchor corridors. Amber marked reduced throughput. Red meant closure, with the unmet mass accumulating beside each node in tonnes per hour. When Halvek removed the holds from Brine's chain in the model, corridor capacity vanished in sequence. Refrigerated drug shipments stopped at Nacre. Sterile membrane stock failed to reach a dialysis habitat beyond Hush. Grain cultures bound for Sable remained on a dock whose reserve power would last eleven days.

"Restore the marker," said Senior Analyst Brev.

Halvek did. The medical systems brightened. A different warning grew around the anchor chain.

Projected shear energy had risen another fourteen percent.

The analysis room carried no windows. Bulkheads thick enough to protect the cruiser's command core turned the air dry and warm. Six analysts occupied recessed stations around the table, each working from Brine's independent records and the Charter's full cage archive. Three security officers stood at the hatch. Nobody had asked for them. Their presence had become ordinary after Threadbare left Nacre under stolen keys.

"Run the model without Brine's release test," Halvek said.

Brev removed the new data.

Projected failure spread widened. The center estimate dropped by six percent, but its uncertainty doubled.

"Now omit Tern."

The prediction lost its narrowest constraint. Tern's dead had measured what happened when a cold-shear cut met an active hold. Without those sixty-three bodies in the arithmetic, the system looked safer because it knew less.

Halvek folded his hands behind his back. "Restore all evidence."

The chain returned: twelve anchors, repeated hold commands, increasing filament stress, and an incoming migration gradient moving toward the Reach. The analyst model did not describe animals. It treated each hollow as a nonlinear mass topology trapped inside a resonator cage. That language required no sympathy. Its conclusion still refused him.

Each hold preserved immediate corridor geometry. Each hold also forced the restrained topology farther from its low-energy contraction state. A later release would return the stored difference through local space. Holding one anchor

changed the next juvenile's timing. Holding all twelve allowed the effects to amplify along the chain.

"How long before a simultaneous failure?" Halvek asked.

"Not simultaneous," Brev said. "Coupled. The first release changes the load arriving at the next anchor."

"Time."

"Best estimate, eighteen to twenty-four days for an initiating event under present hold strength. Adult arrival remains near Day Forty-two. Either could begin the cascade."

"And if we strengthen every cage?"

An analyst at the far station brought up a steepening curve. "We may delay the initiating release by four days. Stored gradient rises enough to triple median infrastructure loss."

"Confidence?"

"Sixty-one percent on the tripling. Eighty-eight that loss increases."

Halvek had sent fleets on worse confidence. He had refused action on better. Numbers did not decide policy merely by becoming available. They described costs. Authority chose which people paid them.

He selected Nacre and shut its corridor in the model.

A column of stranded supply mass grew at once. Nacre fabricated seal membranes for thirty-eight percent of the Reach's older habitats. Local reserves differed by station because peacetime contracts rewarded lean storage. At Day Nine, two industrial cylinders began cannibalizing noncritical pressure walls. At Day Seventeen, a hospital network exhausted certified membrane stock. The model did not estimate deaths beyond that point because local substitution data remained incomplete.

"Brine," Halvek said.

Brev closed it.

Food-substrate movements halted across three systems. The convoy distributed some stock among its ships, which improved survival inside Irian Mott's command and worsened it among populations she had not carried. Sable's surface reserves lasted months. Its orbital ring fed on scheduled nutrient concentrate and lacked conversion vats for raw biomass.

"Hush."

Another corridor disappeared. Famine relief ships stacked at a cold depot. Their cargo survived. The people waiting beyond it did not receive a modeled outcome because three local census authorities had stopped reporting.

Halvek stared at that blank field.

Thirty-one years earlier, his relief fleet had waited beside a closed route while

technicians argued over a field instability. He had carried grain for four million. He had watched demand messages shorten as backup power failed at the receiving system. When the corridor reopened, his ships crossed in disciplined order to find distribution stations stripped for heat and roads clogged with the dead.

Eight hundred thirty thousand.

The inquiry had spent fourteen months assigning portions of delay to operators, ministers, local hoarding, and the anchor fault. None of those portions had reduced the number. Halvek learned then that a closed road killed at the far end, beyond sight of whoever defended caution.

Now the roads themselves carried injury.

"Model staged holds," he said.

Brev looked up. "Define staging."

"Reduce restraint after each essential convoy packet clears. Outer stations first where local geometry permits. Maintain full hold only while occupied corridors carry life-critical mass. Publish closure windows to fleet command twelve hours ahead."

An analyst began building the schedule. "Kessa Rho's test indicates reduced outer pressure lowers stress."

"Her test ended with a destroyed transfer spine."

"Because remote hold returned at full output."

Halvek felt every face in the room become careful.

He had authorized that hold. Not the ramp rate, which the automated controller selected according to corridor-restoration rules, but the restoration itself. The distinction mattered to engineering review. It did not repair Brine's spine or remove the acute-stress signature from the records.

"Add a controlled ramp," he said. "No station restores faster than two percent per minute."

Brev entered it.

The projection improved. Near-term corridor capacity fell by twenty-eight percent. Median failure energy dropped by a third against the full-hold case, though it remained far above a clean release. Medical shipments could move in assigned packets. Food substrate would reach Hush and Sable before their reserve thresholds. The final two anchors required continuous restraint until Day Thirty-one to complete the schedule.

Halvek made the analysts turn tonnage into departures. Aggregate capacity forgave delays that actual cargo could not survive. Brev built a queue at Nacre's outbound mouth: membrane rolls first, then sterile catalysts, pediatric suspension stock, two reactor-control assemblies, and a shipment of replacement bearings for Brine's cylinder hubs. Every priority displaced something with a credible claim to life.

A water-recovery plant missed the first window because its truss exceeded the reduced corridor diameter. Breaking it into sections required six days at a yard already running emergency shifts. A crate of blood-growth medium fit beside the membrane rolls but demanded a colder berth than the assigned carrier could provide. Three agricultural barges could cross empty and take substrate at Brine. Loaded, they pushed the corridor beyond the partial-hold margin.

"Put cold cargo aboard the relief cutters," Halvek said.

Brev reassigned their magazines and crew quarters. "That removes two beam platforms from cage enforcement."

"They can enforce after delivery."

"Or the route can change while they are beyond it."

"Then they remain where the medicine leaves them."

The model accepted the sacrifice without remark. Two cutters shifted from Charter force to cargo capacity. Their command crews would object. Their engineers would improvise refrigeration around weapon coolant loops. Neither inconvenience outweighed eleven thousand doses expiring on a dock.

Next came people. A mining habitat near Nacre requested evacuation lift for eight thousand after local route insurers canceled coverage. Sable's orbital director requested berths for ring specialists but not their dependents. Brine submitted forty-three thousand vulnerable residents through its own assembly, with family units kept intact even when that reduced packing density.

Halvek rejected Sable's separation request. "Specialists travel with registered households."

An analyst said, "That costs seventeen hundred berths."

"It prevents skilled labor from refusing embarkation. Count usable departures, not seats."

He assigned the mining habitat half its request and sent fabrication stock for additional shelter. No line on the table showed how the refused half would read his decision. Capacity could measure a berth. It could not measure the difference between a person left with tools and a person left with nothing but an official explanation.

At Hush, two aid ships competed for the same opening. One carried grain cultures to a population of nine hundred thousand. The other carried fever suppressant for a much smaller moon where an outbreak had already begun. Sending the suppressant first delayed the cultures by fourteen hours. Sending grain first exhausted the moon's clinical stock.

"Split the opening," Halvek said.

"Transition loss leaves neither ship enough corridor duration," Brev replied.

"Transfer the clinical cargo to a cutter."

“No compatible cold rack remains after Nacre.”

Halvek studied drive specifications. “Dock the aid ships nose to nose. Move one sealed treatment module and its power cell. The grain carrier has reserve refrigeration for seed cultures.”

The analysts rebuilt the load. Fever suppressant crossed with the grain while its original ship waited for the next window. A problem that appeared binary at system scale yielded to hardware and twelve hours of cargo work. This arithmetic justified command in Halvek's mind. Someone had to see across routes without forgetting that solutions still passed through hatches.

Then Brev applied uncertainty. One delayed tug erased the transfer margin. A resonator ramp two minutes slower stranded both carriers. Local traffic not reported to the Charter consumed seven percent of the first window at Nacre and twelve at Brine. The clean schedule frayed into branches, each with a different small disaster.

“Publish reserve slots between packets,” Halvek said.

“That reduces delivered mass by another nine percent.”

“It also keeps one error from becoming a closure.”

Brev inserted the gaps. Halvek watched essential freight fall below requested totals in every system, yet remain above the minimum bands his logistics staff trusted. Enough did not mean whole. It meant the point at which people retained several bad choices instead of one fatal outcome.

He ordered the analysts to stop displaying totals and run the schedule as dispatch. The table replaced colored mass with named hulls, departure crews, docking collars, and clocks. Every abstract reserve acquired machinery capable of breaking.

The first simulated window opened at Nacre. Relief Cutter Patient Fire carried membrane rolls in its emptied missile bays. Its weapon coolant kept the cargo cold, but the improvised rack shifted the ship's center of mass beyond the cutter's certified route profile. A traffic controller could either reduce corridor width to protect the cage or admit the cutter at a load that violated the staged-hold limit.

“Break the shipment,” Halvek said.

Brev divided the rolls among three smaller craft. Two lacked contamination seals. The third belonged to a mining company whose crew refused Charter requisition without written indemnity for lost contracts.

“Grant it.”

“From which reserve?”

The command table opened Charter liability accounts. Tern claims had already frozen one. Brine's transfer-spine damage would consume another if the local authority prevailed. Halvek moved the indemnity against fleet maintenance.

A warning appeared beside Continuity's replacement radiator order.

“Accept the delay.”

Brev executed. The membranes crossed in three packets. One arrived nine hours later than the hospital network's request and still inside its physical reserve. The model marked the outcome survivable.

The second window opened at Brine. Agricultural barges waited beyond the reduced throat while forty-three thousand evacuees crowded transfer spines. The schedule could pass two empty barges or six passenger ferries. Food substrate aboard the barges would sustain three isolated systems. The ferries carried people whom Brine had already selected as vulnerable.

Halvek refused the model's optimization prompt. “Show mixed loading.”

Passenger seats replaced substrate tanks badly. One ferry could take sealed culture pods in its baggage spine, but the added mass reduced life-support reserve. One barge could carry suited passengers in a service drum never certified for inhabited passage. An analyst built both options and tagged their hazards.

“Do not put people in a freight drum,” Halvek said. “Strip baggage from the ferry. Culture pods take the spine. Personal mass receives a later lift.”

Brev looked at the passenger list. “The later lift remains uncertain.”

“Put family records and essential medicine with the travelers. Store personal effects locally under claim.”

“What qualifies as personal?”

Halvek almost answered by mass. He saw how the answer would travel: a dead wife's tools, a child's archive, a household's seed packet entering one column because command lacked time to learn its name.

“Brine delegates decide,” he said. “Give them the weight cap.”

That decision cost twenty-two minutes. The ferry reached the corridor inside the reserve slot by less than three. The culture pods arrived warm but viable. The people left luggage behind under a promise no model could guarantee.

At Hush, the staged ramp failed its first test. A local resonator controller reported two percent reduction while an old power amplifier continued compensating below the monitor layer. The corridor appeared compliant until a grain carrier entered. Then the cage corrected against the carrier's mass and erased half the reserve gap.

Brev froze the run. “One unreported control layer.”

“Would inspection find it?”

“Only if the local crew opens the amplifier table. Charter certification reads the same monitor.”

Halvek sent a hypothetical order to inspect every amplifier in the chain. The labor estimate reached nineteen thousand work-hours. The first packet schedule slipped four days. Sterile stock crossed its expiry threshold.

"Inspect active-window stations only," he said. "Require two local signatures on raw output."

"Routekeepers now share the full reason for the ramp."

"They share the beam limit."

"Without the amplification model, they cannot evaluate why a hidden compensator matters."

Halvek heard the distinction. An engineer told only what limit to obey could find a violating table. An engineer shown what failure the limit prevented could challenge the schedule itself.

"Give them local shear projections," he said.

Brev did not move. "The local projection contains the terminal slope."

"Crop it after the active window."

"You are asking technicians to sign a trace whose ending we remove."

"I am asking them to verify present hardware."

The analysts stayed silent. Security at the hatch made that silence expensive. Halvek dismissed the officers to the outer passage. The hatch sealed behind them, leaving the room no freer and less able to pretend otherwise.

"Run it with the cropped trace," he said.

Hush's local crew discovered the hidden compensation and disabled it. The grain carrier crossed. In the simulation, the routekeepers saw enough to perform the immediate work and not enough to know the schedule ended beyond cage tolerance.

Halvek watched the outcome settle into green.

The model advanced to Day Twenty-three. A dialysis habitat received membranes. A fever moon received suppressant. Brine moved vulnerable families. Three systems gained food cultures. At every step, omissions narrowed the information available to people carrying the risk.

He could publish the full analysis and lose control of the windows before those shipments moved. He could restrict it and preserve departures purchased with another, larger failure. The table offered no clean branch, only different distributions of truth and time.

"What happens then?" Halvek asked.

"The model stops producing a stable path," Brev said.

"Because of adult arrival?"

"Because cumulative holds amplify the terminal release beyond current cage tolerance. The adult narrows the interval. It does not create the accumulated load."

The sentence entered the room without accusation. Halvek heard one anyway.

A communications officer appeared at the hatch. "Marshal, three cutter captains request immediate conference under force-safety article nine."

"Here."

"They asked for private audience."

"Then they can ask again in front of the arithmetic."

The officer admitted Captains Vale, Osei, and Rusk. All three commanded cutters assigned to the anchor cordon. Vale had served under Halvek for nineteen years. Osei had extracted two ferries during the Tern failure. Rusk's Ward of Glass currently carried survivors from Brine's broken transfer spine to a pressure clinic.

They stopped opposite the table.

Vale spoke. "We have read the Brine feed."

"So has every routekeeper with a working relay."

"We have also read your restoration order."

Halvek gestured toward the projection. "Then you understand why we require controlled staging rather than local experiments."

Osei leaned over the table. "I understand our beam caused the load spike."

"An automated ramp caused it after my lawful order to restore a civilian corridor."

"Our beam carried the ramp."

"Your cutter did not control the rate."

"That is not comfort to the people we pulled out of the staging tube."

Rusk watched the model rather than Halvek. "What do the red bands mean?"

"Projected lens shear under present holds."

"And the black systems?"

"Supply failures under immediate closure."

Vale's jaw shifted. "So Rho has the biology right."

"The model accepts her measurements. It does not establish intelligence, rights, or a safe network-scale method."

"She has not claimed intelligence."

"She has claimed authority to unfasten twelve anchors serving eleven-point-eight million people."

"Has she?" Vale asked. "Her open broadcast asks whether cages carry the load."

Halvek disliked questions framed to reduce a command problem into wording. "She stole Charter keys, breached impound, and initiated an unauthorized release at Brine."

Osei said, "A partial release that lowered stress before we reversed it."

The security officers near the hatch adjusted their stance. Halvek let them. He had not reached Marshal by confusing disagreement with mutiny. He had also not kept fleets alive by allowing command to become a seminar.

"What remedy do you propose?" he asked.

Vale glanced at the other captains. "Suspend remote holds. Put local routekeepers under recorded safety authority. Offer Threadbare protected approach so Rho and Sel can work with our analysts."

"Immediate suspension closes active corridors without a distribution plan."

"Then issue the plan and release the model."

Brev's hands stopped above her console.

Halvek said, "Which model?"

"The one on this table. Full assumptions, loss bands, and the part showing restraint worsens the final failure."

Rusk looked toward Vale. He had not expected the last demand. Osei had.

Halvek understood their arrangement. Vale would spend rank on the policy challenge. Osei supplied moral force from Tern and Brine. Rusk represented the uncertain captains who needed proof that dissent could survive contact with authority.

He brought up the staged schedule. "This model will accompany operational orders at restricted classification. Public release would trigger unilateral closures before supply packets clear. Brine's local team has already shown that routekeepers will act without network coordination."

"Public concealment will trigger the same thing when they learn," Vale said.

"They have incomplete evidence."

"They have the pulse in their hands."

"A load trace does not allocate medicine."

"No," Osei said. "People do."

Halvek walked around the table until no projected system lay between him and the captains. "You each command a cutter because the Reach requires decisions under incomplete evidence. At Tern, I delayed a cut to clear a convoy segment. Sixty-three died when the systems overlapped. If I had allowed the cut at once, ships in the corridor might have vanished with it. We cannot count the dead from a path not taken. We can count the people dependent on the corridors now."

Vale met his gaze. "And later?"

"Later we open in stages."

"The final release still exceeds tolerance."

"By then the exposed populations will have food, membrane stock, and evacuation lift. Capacity changes what later costs."

Rusk spoke for the first time since Vale's demand. "You are buying days."

"Yes."

"With a larger failure at the end."

"With fewer people trapped beside it."

Osei shook her head. "Unless Sable or Nacre acts outside your schedule."

"That risk argues for command, not its abandonment."

Vale removed the Charter control seal from his collar and set it on the table. "I will not project another remote hold against a contracting hollow."

The words carried no flourish. Vale placed eighteen years of service beside a column of projected deaths and waited.

Halvek gave him one chance. "Withdraw that refusal."

"I cannot."

"You can. You choose not to."

"Yes, Marshal."

Halvek called the security officers forward. "Captain Vale, you are relieved of command pending force-safety review. Your executive officer will take Palisade. You retain quarters and communication access under observation."

Osei stepped between Vale and the officers. "If refusal to injure a living structure voids command, my cutter needs the same review."

"Have you refused an issued order?"

"Not yet."

"Then do not manufacture courage from an order you have not received."

Her face hardened. Rusk touched her sleeve and moved her aside. Vale surrendered his sidearm and went with security without resistance.

Halvek returned to the table. "Captains Osei and Rusk remain in command. They will carry the first medical packets through the staged windows."

Osei stared at him. "And if you order full hold?"

"You will obey or be relieved before your hesitation places a ship inside uncertain geometry."

Rusk asked, "What happens to Threadbare?"

Halvek marked Orison Gap. Three black anchors formed a narrow staging volume between Brine's outgoing line and the obsolete corridor beyond it. The convoy would need to cross that geometry. So would Kessa, if she continued along the chain.

"Threadbare will be impounded at Orison Gap," he said. "Cold weapons only unless fired upon. Preserve its crew, samples, and independent records. Accord of Dust will resume the assigned fixed route after its Brine lift clears."

Osei said, "Captain Mott may not accept compulsion."

"She carries four hundred ten thousand people. She accepts constraints every minute."

When the captains left, Brev kept her eyes on the table. "How much of the amplification analysis enters the packet schedule?"

"All assumptions required for safe execution."

"That does not answer the classification field."

Halvek reached across her station and selected RESTRICTED COMMAND MODEL. Public route notices would show reduced capacity, safety inspections, and staged holds. They would not show the rising terminal shear or the conclusion that every hold increased it.

Brev's voice lowered. "Routekeepers will compare notices with their own records."

"By the time they complete the comparison, the first packets will be through."

"And after the last?"

"After the last, we close what we can and release what we must."

He authorized the schedule. Across the Reach, route windows changed from green to amber. Medical captains received departure times. Food carriers received mass caps. Cutter crews received beam limits and local ramp rules. For the next eleven days, the network could move enough material to give isolated systems choices beyond panic.

Halvek stored the full model in the command vault. The display requested a suppression rationale.

He entered: PREVENT UNSYNCHRONIZED CLOSURES DURING ESSENTIAL DISTRIBUTION.

The public packet still showed amber route windows. Its terminal-shear field had vanished.

A new alert crossed the operations table before the vault sealed. Sable Anchor Authority had rejected the staged reduction order. Its director cited orbital-ring dependence, traffic density, and local emergency powers.

Halvek opened the live cage plot.

All nine Sable resonators burned above Charter limits. A local command had doubled hold strength without waiting for his schedule. The projected shear band climbed so fast that the table changed scale twice.

The standard eighteen-to-twenty-four-day forecast assumed holds inside certified range. Sable's phase slippage erased that assumption. Its initiating window contracted to eleven to fourteen days, while projected infrastructure loss rose beyond the model's previous ceiling.

Brev whispered, "They used our reinforcement protocol."

Halvek sent a direct override. Sable refused it.

On the Reach display, the black system he had meant to save brightened around a captive point, and every neighboring anchor inherited the added load.

Chapter 14 — The Dead Route

The obsolete corridor accepted Threadbare's grapple as if it had been waiting a century for weight.

Kessa watched the jaw close around a cage strut furred with black frost. No strain warning followed. The strut shifted six centimetres and stopped against something hidden inside the dark. Sena killed their approach thrust before the old hardware could pass the load into the tug.

"Grip is clean," Kessa said.

"Everything about that sentence troubles me," Sena replied.

The sealed route hung beyond Brine's traffic plane, outside the line Halvek's cutters could reach without changing vectors. Its registry called it Corven Auxiliary Four. No destination appeared on modern charts. The paired anchor had vanished from service records after a collapse ninety-six years earlier. Charter memorial language described a natural vacuum event, seventeen lost ships, and the heroic closure of unstable geometry.

No chart mentioned the cage still wrapped around the dark.

Threadbare drifted beside a wheel of century-old resonators. Their housings had split under impacts and thermal cycling, exposing coils thicker than habitat trunks. Repair drones floated dead in their recessed nests. A service platform remained attached on one side, bent into a shallow arc that followed no sensible rotation. Stars behind the center stretched into thin amber hooks.

Kessa put her palm against the manual console. Tomis's torque key sat in its diagnostic socket, holding raw clocks outside the navigation system. The brass had warmed under her hand during their approach.

"Any load?" she asked.

Pell answered from the instrument bay. "Static gradient. No three-beat structure. Nothing propagating."

Anu leaned between the couches to inspect the cupola. "The topology still carries tension."

"You said corpse."

"I said the filament sample lacked active conduction. The larger structure could be fossilized topology around an adult carcass."

Sena glanced back. "I liked corpse. Corpse has boundaries."

Kessa enlarged the service platform. "We go in on line. No cage reference for position. Vasken stays with the drums."

The crew had already heard Halvek's seizure order. Two Charter cutters were turning toward Orison Gap to meet them. Every hour inside a dead route narrowed their departure margin. That did not make the find optional. Brine's published

pulse had told routekeepers what the living chain carried now. Corven might show what happened the last time humans refused release.

Kessa suited in the forward lock with Anu and Sena. The pilot objected to leaving the cupola until Kessa pointed out that nobody else could read the old cage's manual attitude marks. Sena objected again on principle, then passed control to Pell.

They crossed on separate tethers.

Frost gave way under Kessa's boots when she reached the platform. The flakes did not disperse. They curved around a buried gradient and settled against the underside of the strut, making a second floor where none belonged. She fixed a handline between two structural ribs and tested every anchor with her full suited mass.

Anu arrived carrying a field spectrometer and sterile corers. Sena brought a pilot's ranging prism older than Kessa.

"Your prism belongs in a museum," Kessa said.

"So does this route. They may recognize each other."

The platform's inspection hatch had fused shut. Kessa worked a cold wedge into the seam. Its metal resisted until Sena braced beside her, then tore free in a slow curl. No air escaped. The compartment beyond had lost pressure before anyone sealed the route.

Their lamps found a maintenance gallery full of restrained motion. Tool bags hung from loops. A ceramic mug floated above a console, fixed there by a small local gradient. Dust had gathered in slanting bands along the walls. Kessa's first step pulled it sideways.

"Follow my boots," Sena said. "Down changes across the gallery."

They moved from rail to rail. Dead screens carried Charter seals over manual access panels. Kessa opened the nearest with Tomis's key. Its old teeth fit the emergency socket because the Charter had preserved tool standards longer than it preserved explanations.

A mechanical log wheel turned once.

DATE: RS 2321.

EVENT: VACUUM TOPOLOGY INSTABILITY.

RESPONSE: FULL RESONATOR HOLD.

The next entry repeated the response. So did the next fourteen.

Anu counted intervals. "Thirty-one hours from first instability to collapse."

Kessa turned the wheel farther. "Hold strength increased after every excursion."

"Any release attempt?"

"None logged."

Sena aimed her prism through an observation slit. "Something lies across the inner station ring."

Kessa looked.

At first she saw only bent stars and the thin ribs of old cage machinery. Then Sena adjusted the prism to cancel one layer of lensing. A broad form emerged behind the hardware. It did not present a surface. Filament lattices held traces of baryonic matter through a volume kilometres long, flattened where resonator beams had pinned it. The shape curved around the route center like a body arrested halfway through turning inside out.

An adult veilback had died inside the cage.

The phrase felt too clean for what remained. Its effective body continued through folded geometry their eyes could sample only in slices. Some filaments had mineralized into pale sheets. Others ended at blackened knots where old fields had burned them. Around the central curve, nine repeated depressions matched the station wheel.

Kessa crossed the remaining gallery toward the observation lock. "I need the inner rail."

Anu caught her tether. "We need a field map before entry."

"The cage has no power."

"The carcass does."

"Carries," Sena corrected. "Nothing here is doing work on purpose."

Anu accepted that with a nod. "Residual topology can still cut her trajectory."

Kessa stopped. At Nacre she had trusted familiar hardware until it moved around an unfamiliar life. Here, familiarity carried less authority than caution.

They deployed six ranging beads through the lock. The first drifted inward and vanished behind a fold. The second reappeared eight metres above its projected line. Beads three and four found a narrow path toward the inner rail. Five stopped in open space. Six circled a dark filament trace and came back toward the gallery.

Sena marked the path by hand. "We follow three. No thrusters after the second turn. Tether pulls only on Kessa's call."

"You are enjoying this," Anu said.

"I enjoy geometry that admits it wants us dead."

Kessa led through the lock.

The inner rail passed under her gloves as smooth ceramic, then rough alloy, then a patch made from a hull plate whose faded lettering belonged to one of the seventeen memorial ships. Someone had cut the plate after the collapse and used it to brace the cage. The Charter had returned here after the deaths. It had repaired enough hardware to seal the body inside.

A resonator shoe loomed ahead. Its field plates had melted at the inner edge.

Pale material crossed them in parallel bands. Kessa set her lamp low and traced each band around the housing.

They converged on a compressed filament bundle.

"Scarring," Anu said.

Kessa removed a flexible scale from her kit and measured the intervals. The first injury ran beneath the original plate. The second crossed a reinforcement installed during the final holds. Later burns cut through both. Every increase in cage strength had driven the field deeper into the same tissue.

They followed the compressed bundle toward the next station. The inner rail ended where collapse had twisted two cage sectors past each other. Sena anchored her ranging prism to the surviving flange and projected a path through the overlap. It required Kessa to pull herself under a severed bus bar, cross six metres without touching the dark fold below, then catch a maintenance ring that appeared displaced from its actual load point.

"Your left hand will miss by half a metre," Sena said.

"Useful hand?"

"The one attached to you."

Kessa launched from the bus bar. The ring looked close enough to strike her visor. Her glove passed through its apparent position and closed on empty space. She let her shoulder turn, reached where Sena's mark indicated, and caught cold alloy beyond the image. Her tether tightened a moment later.

Anu crossed with less grace and more complaint. The sample case clipped the bar but stayed sealed. Sena came last, reeled along both tethers as if the path had never lied.

Beyond the overlap, Resonator Three had split open from inside. Its field plates pointed away from the adult core. Melt had pooled on the outward edge rather than the power-feed side. Kessa crawled into the housing far enough to reach an intact service tag.

"Last replacement came fourteen years before collapse," she said. "Rated output twice the original station design."

"Reinforcement program," Anu replied.

"Not ordinary life extension. They rebuilt the field throat and left the cooling loops unchanged."

The loops had burst under repeated full-power holds. Their frozen working fluid formed blue pebbles around the housing. Beneath those pebbles, a filament sheet carried nine parallel burns. The oldest marks had rounded edges. Later ones cut narrow and deep, with no repaired tissue between them.

Kessa photographed the power rating, plate orientation, and every visible injury. She placed a scale beside one groove without letting it touch. Anu sampled residue from the plate rather than the body. Sena mapped where each scar pointed

through the folded geometry.

At Resonator Six, they found a different failure. Its outer housing remained intact. Someone had added three mechanical braces between the station and inner rail, likely to stop the unit from walking under load. Each brace had bowed toward the adult. The fasteners showed fresh-looking shear faces protected from oxidation by vacuum.

"Hardware moved before the final event," Kessa said. "They knew the load came from inside."

Anu angled her lamp across the brace feet. Inspection dye still marked the bolt edges in alternating colors. "They measured it more than once."

Sena found a stamped maintenance code beneath one foot. "Progressive displacement. Assigned corrective action says increase capture stiffness."

Not one record called the structure a body. Workers had nevertheless traced its movement, reinforced against it, and watched the same points move again. Vocabulary had failed long before the cage did.

Kessa sent the three station maps to Threadbare. Pell aligned their coordinate frames while she remained on the rail.

"Send me Nacre's positions," Kessa said.

Pell overlaid them in her visor. Nine nodes. Same radial offsets. Same asymmetry near the core. Tern's archive followed. Lark-3 came last from the hidden log inside Tomis's key.

The cage scars aligned.

Not approximately. Each route had used the same resonator geometry against the same stage of development. Engineers had standardized a wound across one hundred sixty-eight years, improving field stability while juvenile bodies grew around the pressure.

Anu took a corer sample from mineralized filament. The material resisted, then fractured along concentric layers. "No active repair at this site."

"Try farther out."

They moved along the inner rail. The adult's topology widened beneath them. Between two resonator shoes, the filament sheets had separated into long vanes aimed toward the corridor axis. Their arrangement resembled the early stages of something unfolding.

Anu's breathing changed over comms. "Do not touch those."

Kessa held still. "What do you see?"

"Growth fronts. Or the last state of them."

"Toward the paired anchor?"

"Outward from the adult core." Anu sent a model to their visors. "At juvenile scale, filaments close around injury. These sheets did something different. They

built successive surfaces, each larger and less dense. A developmental transition.”

“A molt,” Sena said.

Anu disliked metaphors, but she did not reject the word. “A topology change consistent with a molt. The adult started it here.”

Kessa looked down the long pale vanes. Three had opened. Six remained folded against the body, each trapped under a resonator node. The cage had held one stage in the geometry required for a human corridor while the animal tried to become another.

“What stopped it?” she asked.

Anu moved her model backward. “The outer growth fronts lack incoming filament reinforcement. If adult molt depends on juvenile release across the chain, those contributions never arrived. The cage also suppressed local expansion. Either condition could prove fatal. Together, they left no viable path.”

Kessa thought of twelve living hollows feeling the migration pulse through tightened fields. “Its calves never came.”

“Juveniles,” Anu said automatically.

Sena touched one gloved finger to a scorched resonator plate. “Calves works today.”

The dead route changed scale in Kessa's mind. She had entered expecting evidence of Charter suppression. Evidence sat everywhere: full-hold logs, repaired seals, repeated burns, a memorial that named vacuum while hiding a body. But the adult's death reached beyond the cage around it. Every juvenile pinned elsewhere had failed to join this molt. The route network had interrupted an entire migration and built ninety-six years of official history over the remains.

Tomis had heard the beginning of the next call at Lark-3.

Kessa pulled the brass torque key from her suit pouch. She had removed it from the console before crossing because leaving it aboard during an impound risked losing the complete log. Its edges caught her lamp.

“He knew,” she said.

Sena turned from the plate. “He knew the anchor moved.”

“He ordered evacuation before the hold.”

“Yes.”

“This proves why.”

“It proves what happened here.”

“The signatures match.”

“Kessa.”

She heard the warning and resented it. For twelve years, the Charter had made Tomis's judgment look like panic from an apprentice who failed to understand a

machine. The corpse beneath her carried cage burns at the same positions. Corven's holds had escalated exactly as Lark's automatic system escalated. A line could connect them clean enough to cut with.

Sena moved closer until their helmet lamps crossed. "You want this dead animal to testify for him."

"It can."

"No. We can measure it. We can publish what the hardware did. Tomis made the right call because his instruments and his hands gave him enough to act. Do not make his rightness depend on a corpse delivering your verdict ninety-six years late."

Kessa closed her fingers around the key. "The Charter blamed him."

"We have his log."

"They buried it."

"Then unbury it. Today we still have living cages and cutters turning toward Orison. Repair the present thing."

The old instinct in Kessa wanted to argue that truth required finishing. Sena had named a worse habit: Kessa treated grief like a damaged assembly, waiting for the correct part to let her close the housing. Tomis would remain dead after every field matched. The work ahead did not need his absolution. It needed his accurate evacuation order and the proof that the automatic hold overrode it.

Kessa returned the key to her pouch. "Pell, copy all logs. Raw wheel images, field map, memorial registry, and cage geometry."

"Already on three stores."

"Send one open."

"Charter interception risk."

"Send it anyway."

Anu crouched beside a filament sheet where its edge had fractured. Fine transparent strands lay inside the mineral shell. She touched them with a conductivity probe.

A shallow response crossed her display.

Kessa leaned over. "You said no active repair."

"At the scars. This material retained structure inside the fossilized layer."

"Living?"

"No metabolism we can detect. Think of an unloaded spring made from biological architecture."

Sena said, "You told us not to think in metaphors."

"I told you not to translate pulse timing into speech. Springs remain permitted."

Anu excised a narrow strand from the fractured edge. It kept its curve after

separation. Under polarized light, its layers ran from the outer surface toward a dense inner thread.

"This might preserve growth order," she said. "The living samples close too quickly for us to see where regeneration begins. Mineralization froze the sequence."

"Take enough for the bench," Kessa said.

"Enough means two strands. We are not salvaging it."

That correction landed where Sena's had. Kessa stowed her unused corer.

They continued to the central observation point. A memorial plate had been fixed there after the collapse, polished metal facing the corpse its text denied.

CORVEN AUXILIARY FOUR

SEALED AFTER NATURAL VACUUM EVENT

SEVENTEEN VESSELS LOST IN SERVICE TO THE REACH

THEIR PASSAGE SECURED OURS

Below the inscription, a later hand had scratched three short marks into the metal. The cuts lacked official symmetry. They might have recorded work shifts, dead friends, or nothing beyond a tool slipping under load. Kessa photographed them without assigning meaning.

Pell called from Threadbare. "Two Charter cutters revised course. Arrival at Orison Gap in thirty-one hours. We have seven before they can close our clean departure line from Corven."

Sena checked the hand-marked path. "Time to leave."

Anu sealed the strands and one mineral fragment in separate tubes. "One more field sweep."

"Five minutes," Kessa said.

They placed recorders against three unfolded vanes and three trapped ones. Residual gradients differed sharply. The opened structures carried tension outward toward the dead corridor axis. The folded vanes held it close to the core. Across the model, one conclusion hardened: the adult had begun to molt and died before it could complete the change.

No intention entered the finding. No last message waited in the fossil. Biology had left load, growth, injury, and failed development. That evidence asked nothing of humans. It described what their machines had done.

Kessa took a final reading at the nearest cage scar.

The detector line jumped.

She expected an instrument fault. Then all six recorders moved together.

Pressure rose through the inner rail. It released, returned, released, and rose a third time. The three-beat load crossed the dead adult from the far edge of its

folded topology to the vanes aimed down the corridor.

"Fresh gradient," Anu said. "External source."

"Adult return?" Sena asked.

"Consistent with the wake map. Stronger than Brine."

The mineralized sheets flexed.

Not life returning. Stored architecture accepted the incoming gradient and passed it along the path it had once tried to build. Frost lifted from the old cage. The memorial plate trembled beneath Kessa's glove.

Pell's voice sharpened. "Anchor response ahead. Obsolete station at Orison just drew power from a dead bus."

Kessa turned toward the black corridor mouth. Far beyond it, too distant for unaided sight, the next juvenile had received the load. Its cage woke in answer with no human command.

Along the corpse, the unfinished molt opened one pale vane wider and sent the pulse onward.

Chapter 15 — What the Calves Remember

Anu ruined Kessa's cleanest cutting tray with a piece of the dead adult.

The mineral strand lay beneath Threadbare's bench field, pale and curved inside a transparent hood. Beside it, living filament from Nacre tightened around a row of ceramic pins. Brine's sample occupied a separate dish because Anu refused to let two juveniles' tissue touch before she understood cross-contamination. Every pulse trough triggered a camera burst and another set of conductivity readings.

Kessa held a lamp beneath the trays. "The dead strand has no active conduction."

"It preserves layer order," Anu said.

"That was true six hours ago."

"It remains true now, with better images."

The repair gallery had become a laboratory by force rather than design. Sample hoods occupied the sealant table. Imaging coils hung from grapple spares. Vasken had surrendered a tool cabinet after Anu threatened to store biological media in the crew refrigerator. Hot insulation and solvent still overpowered the sterile smell.

Outside the hull, Orison's outer anchor turned three black arcs through the cupola view. Its cage had woken when the fresh adult pulse crossed Corven's carcass. The station carried no permanent crew. Charter automation had kept its resonators aligned for emergency staging and occasional military transit.

Two cutters were coming to use it.

Sena floated in the hatch with a navigation slate strapped to one forearm. "We have thirty-one hours before first interception. Twenty-six if they burn reserve propellant. Pell recommends we leave now and mock biology from somewhere less charted."

"Pell has range estimates?" Kessa asked.

"Pell has survival instincts. Range estimates came free."

Anu did not look up. "If we leave before the next trough, we lose the cleanest comparison."

"Of course we do."

Sena pushed into the gallery. "Explain the clean comparison to the person responsible for not being impounded."

Anu enlarged three images. The dead strand showed nested layers around a dense inner thread. Nacre's sample had closed around its ceramic pins in the opposite apparent direction, blurring the order as each layer contracted. Brine's sample still carried damage from Halvek's hold. Its outer surface had split into fine branches.

"Watch the branches," Anu said.

The ship clock counted down to the pulse window predicted from Corven. No one spoke. At zero, the three-beat load entered Threadbare through the grapple drums. The samples moved before the bench instruments registered local gradient change.

Brine's outer branches extended.

They spread along the dish, found the ceramic pins, and joined around them. A second layer formed beneath the first. Only then did the dense central thread thicken. Nacre's sample followed the same sequence, harder to see because its wound had nearly closed.

Anu stopped the recording. "Outward-to-inward."

Kessa replayed it at a slower rate. "Repair starts farthest from the core."

"Regeneration begins at the low-density surface after every migration pulse trough. The new outer layer establishes geometry. Middle structure follows. Core conduction closes last."

Sena studied the dead strand. "And this preserves the same order because its attempt froze halfway."

"Yes."

"Does that tell us how to open a cage?"

Kessa already had the cage diagram over the image. Nine resonators pressed through the juvenile topology at three effective depths. Station manuals numbered them around the wheel, but the animal's filament layers grouped them differently. The widest field nodes held outer structure. Three intermediate nodes compressed denser bands. The core stations carried corridor alignment through the central thread.

At Tern, Kessa had followed mechanical load order. She reduced the stations that carried the largest cage stress, expecting the rest to settle. Halvek's hold opposed her sequence and made every field fight for the same geometry. Even without that interference, Kessa now saw a flaw. She had treated the juvenile like a suspended bridge.

Living tissue repaired from its outskirts after the trough. Release needed to respect that direction.

"Outer three first," she said.

Anu nodded once. "Then wait for full contraction."

"Middle three after the outer layer establishes a free boundary."

Sena tapped the last cluster. "Core triad when?"

Kessa aligned the migration trace with the conductivity curve. During each three-beat pulse, the central thread carried peak load. Immediately afterward, conduction fell into a trough lasting between ninety and one hundred twenty

seconds. The core loosened before regeneration began again.

"During the pulse trough," she said. "Not before it. Not while the next rise starts."

Anu added tissue stress bands to the sequence. "A complete release still needs more time than one trough. Outer contraction takes at least four minutes in these samples."

"Then outer three, wait. Middle three. Core triad on the next trough."

Sena counted on her fingers. "Eight minutes if everything behaves. Eleven if one station drags."

"Nine under median response," Anu said.

"Biology has learned schedules now?"

"No. Kessa needs a number to design around. Nine minutes carries the highest probability if local stress stays below Brine's post-hold state."

Kessa looked toward the three black arcs outside. "We test without cutting. Partial release, outer and middle only. Let the core keep corridor capture."

Sena's expression lost its humor. "On Orison Outer?"

"It woke. Its local controller has no population traffic and no crew to overrule us."

"It also has Charter receivers."

"Pell can isolate the local bus."

"For how long?"

"Ask Pell."

"Pell says every question eventually becomes her problem."

Kessa closed the sample hoods. "That makes her one of us."

They called the crew into the drum passage. Nineteen people fit by using handholds, deck straps, and the open mouths of two maintenance bays. Kessa put the sequence on the wall display. She did not call the test safe. She described failure boundaries: uncontrolled expansion, corridor collapse, remote hold, or a gradient shift beyond the tug's escape margin.

Vasken asked, "What do we gain from partial release?"

"Proof the sequence works at scale. A field map for full release. A timing window we can send to every crew."

"And if it does not?"

"We stop before the core. The cage keeps capture."

Pell folded her arms. "Unless Charter restores the outer stations while the animal contracts."

"Yes."

"How long can I block remote access?"

"Your problem," Sena said.

Pell ignored her. "Local control bus can stay dark to network commands for ten minutes before Continuity's authentication daemon forces a restart. I can extend that by physically pulling the receiver feed. Afterward, the cage reports sabotage."

"The cage already reports an animal as geometry," Vasken said.

"That does not pay my legal counsel."

Kessa waited while they argued. At Nacre, seventeen had chosen to remain when two left. At Brine, every partial release carried six teams' consent. Here, the crew faced a Charter seizure order and an experiment that might close their best route out.

"No one works exterior without a separate yes," Kessa said. "The ship can withdraw by majority. Pell runs the count."

The vote gave fifteen for the test, four for leaving before interception. Of the exterior-rated crew, six accepted positions. Kessa logged the dissent and assigned those four to tug recovery, where their caution might save everyone.

Preparation took two hours and removed several elegant assumptions from Kessa's work card. The first rehearsal used dead switches in the repair gallery. Three crews called their reductions on a shared count, but hand speed spread the commands across six tenths of a second. At cage scale, that delay could pull one outer layer sideways before the other nodes loosened.

Kessa replaced the spoken count with lamp pulses from an isolated timer. Each station team received a mechanical indicator clamped beside its control cover. Green meant reduce. White meant hold position. Red meant cut local power and withdraw. No command traveled through the cage network.

Vasken objected to the timer controlling hands. "We are building another automatic hold."

"No. The lamps advise. You still read your station and stop on bad load."

"Then why not call it?"

"Because my voice reaches you at different delays when the field shifts."

They rehearsed again. This time Five reported a sticky trim wheel. Eight's crew discovered its suit radio dropped packets behind a grapple drum. Two's indicator detached when someone brushed the clamp. Kessa fixed each fault with cord, solvent, or a different hand position. None deserved invention. Ordinary bad maintenance could ruin the sequence more efficiently than Charter opposition.

Anu set biological stop bands on every indicator. She refused to reduce the animal's response to green and red, so the middle screen carried live stress values beside the work cues. A steady decline permitted continuation. Any sharp rise required a local stop even if the timer remained green.

"Workers need a readable instrument," Kessa said.

"Workers also need the uncertainty."

"Give them both."

Pell built a split display: one broad line for change and three small figures for those who could spare attention. The compromise satisfied nobody, which made it practical.

Sena used the delay to plot escape vectors. Orison's three anchors created overlapping bends across the staging volume. A straight burn from Outer led through a region where the tug's apparent heading could reverse while its momentum did not. She marked two curved exits, one toward the dead Corven route and one across the future convoy approach.

"We take Corven if the juvenile expands," she said. "We take the convoy side if Charter arrives early. If both happen, I become religious."

Kessa inspected the plotted loads. "Corven path crosses our deployment tethers."

"Only if you leave them attached."

"We may need recovery pulls."

"Then choose between recovering equipment and keeping the equipment's owners."

Kessa added explosive releases to all six lines. The crew tested each squib electrically, then replaced the live charges and tested continuity again. A failed tether release at Tern had cost four workers the seconds they needed to clear the spindle. Nobody on Threadbare treated line cutting as waste now.

Last, Pell copied the raw data path into Tomis's torque key. If Charter seized the tug, the sequence would survive inside a tool inspectors might dismiss as personal property. Kessa almost told her not to make the key carry another hidden truth. Instead, she checked the diagnostic cavity and returned it to her suit kit.

Orison Outer had no transfer spine. Its nine stations connected through a skeletal service wheel built for automated maintenance. Threadbare approached beneath the cage plane, presenting as little hull as possible to any sudden gradient. Sena flew by hand from the forward cupola. Pell sat beside her with the Charter receiver path exposed behind the console.

Kessa crossed to Resonator Two with Vasken and two riggers. A second team took Five. The third waited at Eight. Anu remained inside the tug, watching filament stress through borrowed station sensors.

The old manual cover opened under Tomis's torque key.

Kessa found the local power train intact. "Two ready."

"Five ready."

"Eight ready."

Pell called, "Network dark in three, two, one."

Orison Outer vanished from Charter control.

No alarm reached them from Continuity. The local cage began one of its own, a pulsing red light on every station. Kessa switched her channel to crew-only.

"Outer three to eighty percent."

She lowered Two. Five and Eight followed within a tenth of a second. The juvenile's outline changed beneath the wheel. Stars that had formed sharp hooks relaxed into wider curves.

"Stress falling at outer nodes," Anu said. "Core stable."

"Sixty."

Fields reduced together. A translucent filament web became visible between Two and the dark center, not from illumination but from its effect on the red star. It tightened without snapping.

At forty percent, the wheel shifted.

Kessa felt the movement through her tether and nearly ordered a stop. Anu spoke first. "Coherent contraction. All outer layers moving inward. Continue."

"Twenty."

No shear struck the station. No stored geometry threw their ships aside. The juvenile gathered its extended topology away from the outer fields, following a route its own regeneration had prepared.

"Outer three off," Kessa said.

She cut Two. The other stations went dark.

The service wheel stayed aligned. The corridor mouth narrowed by eleven percent and held. Under Kessa's boots, the station carried a soft series of irregular tremors. They resembled muscle fatigue more than signaling. She kept the comparison to herself.

"Contraction clock," Anu said. "Do not touch middle stations."

They waited.

Four minutes felt longer outside a cage than any burn. Kessa watched the timer and the filament web. At ninety seconds, its widest branches drew inward. At two minutes, local gradient fell enough for Threadbare to shift eight metres despite Sena's correction. At three, the outer topology settled inside a stable band beyond the middle fields.

A Charter authentication request hit Pell's isolated receiver. Then another.

"Daemon knows we are dark," Pell said. "It starts restart pressure at minute eight."

"Can you hold nine?"

"I can hold until the receiver hardware melts. You will dislike the repair."

“Put it on my list.”

Anu marked contraction complete at four minutes twelve seconds. “Middle layer has free boundary. Proceed.”

Kessa moved to Resonator One, the first intermediate node. Vasken crossed to Four. The other team took Seven. Their tethers ran around the wheel in clean, separate paths.

“Middle three to seventy.”

These fields carried more corridor load. As they fell, the route mouth tightened and lengthened. Navigation beacons beyond Orison doubled, merged, then shifted to new apparent positions. Sena read them aloud so exterior crews would not trust their eyes.

“Forty percent,” Kessa ordered.

A pulse approached along the wake map.

Anu counted its arrival. “Three-beat in twenty seconds. Hold present level.”

The first beat crossed the cage. The juvenile's core brightened on Kessa's field display. The second arrived with a slight delay. The third passed through the loosened outer layers without Brine's ragged stress tremor.

Afterward, conductivity fell.

“Pulse trough,” Anu said. “Core load down thirty-two percent.”

Kessa did not touch the core triad. This test ended before full release. “Middle three to twenty, then off.”

The fields declined. Filament structure moved inward behind them. At zero, six of nine resonators stood dark. Only stations Three, Six, and Nine held the juvenile's dense central thread.

For one second, nothing changed.

Then the juvenile rotated within the remaining capture.

The motion came as a broad reorientation rather than a strike. Bent stars rolled around the core. Threadbare's hull creaked. Kessa's tether pulled her toward the station, never away. The animal had shed the outer cage and aligned its free layers with the fresh adult gradient.

“No shear release,” Anu said. Her voice stayed precise despite the speed of her breathing. “Local energy remained in tissue contraction. External gradient within two percent of pretest.”

Sena called from the cupola. “Corridor remains navigable for light craft. Not for convoy mass.”

“We did not build this for convoy passage,” Kessa said.

“No. But a Marshal approaching with cutters may mention it.”

Pell's daemon timer reached eight minutes. Charter commands stacked behind

the isolated receiver: restore outer hold, restore middle hold, secure local access, identify unauthorized vessel.

“Network back in forty seconds,” she said.

Kessa examined the core field. The trough would last another thirty-five seconds. They could drop the core triad now and complete the release. Every measurement said the sequence had worked. The juvenile's free layers already aimed along the wake.

Anu seemed to read the possibility in her silence. “We did not consent to full release.”

“I know.”

“Neither did the crew.”

“Their decision holds.”

Kessa closed the manual cover over Resonator One. “All teams withdraw. Leave six dark. No cut.”

They crossed back as the network rebooted. Charter control seized the local bus and attempted to restore the outer stations. Pell had removed their ignition permissions at the hardware level. Commands arrived. Nothing powered.

The core triad remained active. The juvenile stayed partially released without shear.

Inside Threadbare, Anu placed the live traces beside the sample recordings. Outward contraction began after the previous trough. Middle release followed once the new boundary stabilized. Core conductivity reached its lowest point during the next trough. The dead adult's preserved growth layers matched every stage.

“What do the calves remember?” Sena asked.

Anu gave her a tired look. “Nothing we can call memory without misleading people.”

“The title in my head can survive peer review.”

Kessa understood what Sena meant. The juvenile did not remember a route, a parent, or a human injury as a person would. Its tissues retained a developmental order shaped across migrations older than the anchor network. Cut outside that order, the structure fought damage. Released along it, the body gathered itself.

Kessa built the work card.

OUTER THREE: reduce together; confirm full contraction.

MIDDLE THREE: reduce after outer boundary stabilizes.

CORE TRIAD: release during pulse trough only.

ABORT: any restored hold, asymmetric field return, or rising local shear.

The next requirement sat outside biology. Nine minutes demanded control silence across the entire cage network. One Charter beam could repeat Tern or

Brine. Local breakers could stop station commands, but Continuity projected holds through external relays. Every routekeeper along the chain would need a network dark long enough to isolate all remote authority.

Sena read the work card. "Halvek will call this sabotage."

"He can call after nine minutes."

Pell asked, "Encrypted to union captains?"

"No." Kessa opened a public route-safety channel. "Every routekeeper. Every convoy bridge. Charter analysis too."

"Then they can intercept us faster."

"They already know Orison."

Kessa attached raw timings, crew votes, local geometry, tissue images, and the abort rules. She included the partial release result without claiming safety beyond what they had done. Anu added a warning in plain terms: the three-beat variation marked biological stress and timing, not language.

The destination list filled the screen. Nacre. Brine. Hush. Sable. Eleven other route stations answered the open relay. Accord of Dust accepted a copy through its convoy channel.

At the end of the list waited Continuity.

Kessa addressed the sequence to Marshal Halvek Enro by name and pressed the public send control.

Chapter 16 — The Battle at Orison Gap

Irian placed seventy million tonnes of civilian necessity between Threadbare and the guns.

On the bridge plot, Accord of Dust stretched across Orison Gap as a long truss surrounded by rotating drums, barges, water bladders, seed vaults, and tugs. The three black anchors made navigation uncertain beyond ten thousand kilometres. Halvek's cruiser held above the central plane with nine cutters spread across the fixed corridor mouth. Kessa's small salvage tug waited near Orison Outer, six resonators dark behind it.

Every ship had room to avoid the others. No ship had a route that preserved its purpose.

"Convoy speed down to point-zero-two," Irian ordered. "No automatic correction inside the anchor overlap. Distribute manual slates."

Her navigation pit repeated the instructions to four hundred captains and tug masters. Pale vectors appeared ship by ship rather than as one fleet solution. A delay at the far edge already bent the formation. Habitat drums could not stop as quickly as cutters. Loaded barges could barely turn before their departure point became history.

Halvek's face appeared above the central plot.

"Commodore Mott, reduce thrust and open a clear enforcement lane. Threadbare stands under lawful impound."

Irian attached the convoy's public channel to his image. "Your lane crosses three evacuation habitats and two water trains."

"Those units entered after my exclusion notice."

"They entered Orison Gap on the schedule your office issued."

"The schedule directs Accord onto the fixed corridor."

"That corridor now has six powered resonators around a partially released living structure."

"The core triad preserves capture and navigability. My analysts confirm a reduced-mass window."

"I carry no reduced-mass version of this convoy."

Halvek's gaze moved aside, likely toward his own capacity table. "Detach the slow barges. Charter tugs will secure them until the corridor returns to full diameter."

"Your return plan requires reapplying outer holds."

"It requires restoration under a controlled ramp."

"And if the juvenile contracts while you restore?"

"That risk remains below the risk of keeping four hundred ten thousand people in uncharted drift."

Irian looked at the human distribution behind his terms. The nearest civilian drum held eleven thousand evacuees from Sable's unrest, most asleep in shared berths during the maneuver watch. A water train behind it fed six habitats. Two freight barges carried Brine substrate spread deliberately so no single loss could starve the convoy. Halvek saw the same mass. He arranged it into throughput and delay. Irian arranged it into dependencies that moved too slowly to survive anyone's clean order.

"I will not detach life-support freight under armed custody," she said. "I will clear a rescue lane and a negotiation berth. Threadbare may approach under convoy guarantee."

"Rejected."

"Then we remain on present drift."

"You are obstructing a Charter seizure."

"I am moving civilians through a published route."

Marl Quade stood at the edge of the bridge pit with six passenger delegates linked through her slate. The Free Convoy Articles did not cover armed confrontation in useful detail. They did cover involuntary route changes. Every delegate had denied the fixed corridor after Kessa published the release sequence.

Marl muted the external channel. "Delegates hold their vote. No fixed route."

"Tell them to prepare shelters," Irian said.

"They already have."

That reply frightened her more than Halvek's cutters. People had learned the shape of imminent force from bridges that insisted negotiation continued.

A tactical officer marked three narrow lines from Continuity to Orison Outer. Resonator-control beams, not weapons, but each carried enough field power to force the juvenile's cage. Two crossed the convoy's planned motion. One passed through the exclusion cone around Habitat Nineteen, where rotating machinery and passenger modules made any directed energy hazardous.

"Transmit civilian cones again," Irian said. "Hard identifiers on every module."

The bridge sent the geometry to all Charter ships. Eight cutters acknowledged. Continuity acknowledged receipt without accepting the exclusion.

Kessa entered the channel from Threadbare. Her image shook with tug vibration. "Orison Outer cannot take restored field. Filament contraction has stabilized outside six stations. Any hold against it risks shear."

Halvek answered, "Stand down your cutter and surrender cage access."

"My cold-shear cutter remains secured."

"Then surrender control keys."

"No."

Irian cut between them. "Marshal, bring one shuttle to Accord. Leave beam control under local captains while we establish a safe disposition."

"Delay allows Threadbare to flee through unstable geometry."

"Firing makes geometry less stable."

"I have not ordered weapons fire."

He had ordered positions that turned weapons into the next sentence.

Irian opened the tug net. "Cluster chiefs, prepare mass screen Delta. Civilian drives only. No collision vectors."

The order moved six empty cargo shells and four water bladders into the open line between Kessa and the cutters. Their tugs used short burns, slow enough to advertise intent. Behind them, Habitat Nineteen continued its rotation. Irian kept its thrust constant so nobody could claim the drum had maneuvered as cover.

Her tactical officer said, "Screen closes beam lane in three minutes."

"Leave rescue gaps."

"Any gap wider than a tug gives a cutter sight line."

"Then give them two narrow gaps and publish both."

The mass screen did not protect Threadbare from pursuit. It made every shot expensive to the person who ordered it. Irian hated the use of civilian property as leverage. She hated more the assumption that military geometry remained clean because the civilians moved aside.

Halvek sent a private channel request.

She accepted.

"You served route navy," he said. "You know obstruction invites escalation."

"I know a commander chooses whether to escalate."

"You have placed water reserves inside an enforcement line."

"I placed them on the convoy's minimum-turn path. Your line arrived later."

"Kessa Rho has no authority over the lives her experiment places at risk."

"Neither do you by yourself."

"I hold treaty command."

"I hold convoy command under Articles accepted at Brine. The passenger delegates denied your route."

"Emergency authority supersedes local compact."

"Not aboard my ships."

His expression did not sharpen. Fatigue showed around his eyes instead. "If this formation remains in open drift when Sable's anchor fails, you lose more than barges."

"Then help us turn toward the juvenile wake."

"No chart certifies it."

"No chart certifies a corridor built from injured tissue either."

A warning cut across both channels. Cutter Palisade had launched a boarding package toward Threadbare: two grapples, one drive-disabling beam, and a pressurized security pod. Its new captain transmitted lawful seizure terms on continuous repeat.

"Kessa, evade without crossing the civilian plane," Irian said.

"Working on the word without."

Threadbare rolled under Orison Outer's service wheel. One boarding grapple struck a dead resonator station and locked. The second caught the tug's port grapple housing. Its line tightened between Palisade and Kessa's hull.

Sena burned lateral thrust. Threadbare could not break free without tearing out its own drum.

Irian marked a convoy salvage tug nearby. "Patient Lever, take the boarding line at midpoint. Do not cut. Pull it below the habitat cone."

The tug captain acknowledged. Patient Lever fired across the gap, caught the taut cable with a magnetic hook, and applied downward thrust. Three ships became one load triangle. Palisade's line dragged away from Habitat Nineteen.

The cutter captain increased reel force.

"Warn him the tug has crew aboard," Irian said.

"He acknowledges and orders release."

"Hold the hook."

Patient Lever's drive climbed toward thermal limit. Kessa vented her grapple drum cover and sent Vasken outside on a short tether. He reached the captured housing with a cold cutter, protected from Palisade's disabling beam by the tug's own hull.

A second Charter cutter moved to flank him.

Captain Osei's Last Measure blocked it.

Osei spoke on force channel. "Boarding line crosses a registered civilian maneuver cone. Reposition before applying more load."

Palisade's captain answered, "Marshal's seizure order controls."

"Not my helm."

Halvek came onto the shared channel. "Last Measure, clear the enforcement lane. Palisade, disable Threadbare's main drive at minimum power."

Kessa's tug lay behind the moving water bladders. No direct beam path remained.

Palisade adjusted above the mass screen.

Its first shot struck an empty cargo shell. The beam did not explode it. Heat spread through the shell's frame and dumped into a tug coupling. The coupling warped. One control tug spun away with dead thrusters.

Irian assigned two rescue craft before the crew called for help.

The second shot passed between water bladders and clipped Threadbare's drive plume. Sena killed thrust before the beam could climb the exhaust path into the engine. Vasken's cutter reached the boarding line.

Then Orison's juvenile pulsed.

Three beats crossed the cage and entered every taut cable. The boarding line jumped sideways. Patient Lever rolled under the load. Its magnetic hook held, pulling the cutter's bow off axis. Palisade fired attitude thrusters to correct.

The correction aimed its disabling array through Habitat Nineteen's exclusion cone.

Osei shouted, "Hold fire. Civilian cone."

Halvek said, "Palisade, cease beam."

The order arrived after the captain fired.

Blue-white light crossed the gap. Bent geometry made the path look curved, but the beam traveled directly enough to burn through Habitat Nineteen's outer radiator mast. Superheated coolant entered the drum's rotation plane. A support spoke failed where thermal shock met cyclical load.

The habitat lurched.

Its near passenger module tore from two of six mounts. Pressure doors closed through occupied corridors. One did not close.

Irian's bridge filled with casualty alerts.

"Stop all fire," she ordered on every channel. "Rescue condition across Orison Gap. Habitat Nineteen structural failure."

Palisade ceased. Five other Charter cutters held position. Two continued moving toward Threadbare under grapple authority.

Halvek's face reappeared. "All units cease directed energy. Rescue craft have priority."

The juvenile pulse altered local drift before ships could obey. Habitat Nineteen's damaged module swung outward on four surviving mounts. Its mass crossed the tow line of freight barge Granary West. The barge tug cut loose too late. Cable wrapped its drive frame and pulled the tug into the barge's stern.

Both drives ruptured.

No theatrical fireball followed. The vessels went dark together, their heat sinking into damaged structure while fuel vented in a pale sheet. Granary West began moving toward the central anchor plane with two thousand tonnes of food substrate and a crew of sixty-two.

Irian had no spare acceleration for everything.

“Rescue group One to Habitat Nineteen. Group Two, Granary West. Every other ship holds local drift. Do not chase loose cargo.”

Captain Osei broke formation first. Last Measure turned its armored bow toward the damaged habitat and extended rescue grapples.

Captain Rusk's Ward of Glass followed, matching Granary West without charging weapons.

The executive officer commanding Palisade hesitated beside the cable that had started the failure. Then he released Threadbare, cut his own boarding line, and turned toward Patient Lever's disabled crew.

Osei transmitted on the public channel. “Last Measure declares neutral rescue status. Weapons safe, Charter enforcement suspended until every reachable survivor clears.”

Rusk repeated the declaration for Ward of Glass.

A third voice followed from Palisade. “Neutral rescue status. Boarding order suspended.”

Three cutters had left Halvek's firing formation. Their hull markings remained Charter blue. Their tactical icons changed to rescue white.

Halvek did not revoke their declarations. “Six cutters maintain cordon. Rescue units coordinate with Commodore Mott.”

The distinction prevented complete mutiny and ended his immediate seizure geometry.

Irian took it.

“Neutral cutters, slave rescue plots to distributed control. No central helm assumptions. Habitat teams report pressure sections, not total hull.”

Marl moved into the bridge pit and began reading passenger-module rosters. Her voice gave names to sealed compartments. Habitat Nineteen's crew had isolated the damaged quarter, but three corridors lost pressure before doors closed. Rescue workers entered from both ends with patch skins and line launchers.

Last Measure used its military grapples as stabilizers. One fixed the habitat hub. A second held the damaged passenger module inside a survivable rotation. Osei could not stop the drum without injuring everyone still strapped inside. She matched its movement and let her cutter swing around it.

At Granary West, Rusk caught the barge above its breached drive. The attached tug had folded into the cargo frame. Rescue teams cut compartments free one at a time. Food substrate vented as brown frozen pellets, filling the work volume with obstacles too small for radar and large enough to break visors.

Freight barge Seedline Two tried to avoid the debris. Its pilot chose a hard

lateral burn that carried it across Anchor Central's gradient boundary. The bow continued one way while the stern met a different curve. Structural bolts failed along the cargo spine.

Irian saw the split before the pilot did. "Seedline Two, abandon barge. Tug crews detach now."

Two tugs released. A third coupling jammed. The barge bent around it, crushing the tug's forward lock.

"Cold cutters to that coupling," Irian said.

"No clean approach," her rescue officer answered. "Debris field between us."

"Use the empty water tender as shield."

The tender moved ahead of two rescue tugs, taking frozen substrate and metal fragments across its broad tank. Behind it, cutters reached Seedline Two. They cut the jammed tug free with twenty seconds before the barge's spine separated.

Both halves drifted into the anchor boundary. Lens shear pulled their trajectories apart. Neither could be recovered.

Two freight barges now counted as total losses. Their cargo had been distributed precisely to survive such a loss. Irian felt no comfort. Distribution turned catastrophe into shortage. It did not make the lost food reappear.

Amid rescue traffic, Threadbare remained without main thrust. Vasken had cut the boarding cable, but the disabling beam scarred its drive sensors. Sena could fire only low manual burns before the engine controller tripped.

Halvek's six aligned cutters still held the fixed corridor mouth.

Irian opened a narrow channel to Kessa. "Can you cross behind Orison Outer?"

"Not without a tow through the released layer."

"Can the juvenile tolerate it?"

"Tow mass does not touch the cage. Any restored hold does."

Irian assigned four convoy tugs. "You get one cluster. They tow you along the wake side. No corridor entry."

"That fuel belongs to your turn."

"So does your sequence."

Kessa looked away from the pickup, likely toward Sena. "Accepted."

Halvek called Irian before the tugs attached. "If Threadbare leaves the Gap, you become party to flight from Charter seizure."

"I became party when your beam entered a habitat cone."

"I ordered cease-fire."

"After the shot."

"Then help me preserve jurisdiction for the inquiry."

“Your jurisdiction has guns around my wounded.”

His voice dropped. “Six cutters still answer me. Do not force another crossing.”

Irian examined the plot. Rescue units occupied the space between fleets. Civilian mass filled every weapon line. Halvek could stop Threadbare only by firing through his own neutral cutters or the damaged habitat. He knew it. She knew it. Neither needed to say what command had become.

“You can preserve people or preserve the seizure,” she said. “Not both in this geometry.”

Halvek closed the channel.

The tow cluster attached to Threadbare. Four tugs pulled in staggered formation, each using a manual slate to correct for Orison's shifting stars. Kessa's ship passed behind the partially released juvenile. Six dark stations remained dark. The core triad held a narrow boundary while the living outer layers aligned with the migration gradient.

No cutter pursued.

Rescue lasted nineteen hours.

Irian stayed on the bridge until every pressure section had a status. Habitat Nineteen lost sixty-one people in the torn module and failed corridors. Granary West lost thirty-four across its barge and crushed tug. Seedline Two lost twenty-one. Eighteen Charter personnel died during grapple rescues and drive-compartment breaches. Thirteen people from convoy tugs died in collisions or suit failures.

The certified total reached 147.

A second clerk checked every name against berth rosters, suit beacons, and cutter reports. Three missing workers reappeared aboard a rescue tender before certification. Two duplicate entries came off the list. Irian waited for that work because a dramatic number had no authority over an accurate one.

Irian ordered the number transmitted without categories that softened responsibility. Civilian, Charter, convoy, and cutter deaths belonged to the same engagement. The report named the beam path, the exclusion cone, every later collision, and the shifting anchor geometry. It also named her mass screen. She would not describe water bladders as if they had wandered into a firing line on their own.

Fuel accounting came next. Rescue burns had consumed forty-one percent of Accord's remaining reserve margin. The four tugs towing Threadbare could not return before the convoy turn. Two freight barges and their cargo were gone. Habitat Nineteen required continuous stabilization until a temporary hub brace could be built.

Marl read the totals beside her. “Can we still take Halvek's corridor?”

“Not at our mass.”

“Can we go back to Brine?”

Irian ran the turn solution. Rescue drift, lost tugs, and spent fuel had changed the answer. Returning to the fixed route required more reserve than following Kessa toward the juvenile wake. Even if the convoy surrendered ships and freight, Charter seizure would divide its people from the stores distributed for their survival.

“No,” she said. “We can shelter here until supplies fail, or continue along the chain.”

Marl opened the passenger channel. “Delegates will need the real fuel bands.”

“They get all of them.”

At Orison's edge, Halvek transmitted a final order for Accord of Dust to submit to Charter routing. Irian entered the Free Convoy Articles, the recorded delegate refusal, and the neutral rescue declarations into her reply.

She did not announce independence. No authority in the Reach had a useful category for a convoy carrying its own food, wounded, votes, and route problem beyond every permitted road.

The tow cluster sent Kessa's new vector. It ran along the waking chain.

Irian matched the convoy's next burn to it. Behind them, six cutters guarded a fixed corridor they could no longer use. Three neutral rescue units held Habitat Nineteen together while the last bodies crossed into Accord's morgue.

Every remaining tug fired.

Orison Gap began to recede, and the convoy's only lawful destination receded with it.

Chapter 17 — A Necessary Mutiny

Kessa climbed into Mica Hand through a collar still scarred from the battle.

The cutter had spent the night towing a cracked habitation pod clear of Orison Gap. Carbon dust coated its lock, and a streak of frozen sealant crossed the inner hatch where somebody had closed a fragment wound in vacuum. Orra Senn waited beyond it with one sleeve cut away for a pressure bandage. She offered Kessa her sound hand.

“Your tug brought trouble to my berth,” Orra said.

“Your berth crossed three firing lines to reach us.”

“I like to know the provenance of my trouble.”

Kessa took the offered grip. Orra’s palm carried the hard ridges of an old cable burn. No one aboard the independent cutter had wasted time polishing away evidence of the rescue. Folded stretchers remained strapped along the passage. A crushed Charter helmet sat beneath a net beside three routekeeper tool cases.

Through the pressure door, Threadbare hung against sparse stars with one grapple drum scorched and her forward transponder still broadcasting an impound order. Accord of Dust lay farther out among its barges and habitat drums. Three Charter cutters held neutral rescue positions around the convoy. Six others had withdrawn with Continuity, close enough to remind everyone that neutrality had a range limit.

Orra led her toward the cutter’s machine bay. “They are all here. That does not mean they agree.”

“Agreement would worry me.”

“Good. You are about to meet twelve people who confuse caution with evidence of character.”

The machine bay had room for eight suited workers around an open resonator bench. Twenty-seven crowded it. Captains attended in person when their ships could spare a boat; others stood as flat transmissions on work displays clamped to coolant lines. Every crew responsible for the threatened chain had a voice in the room. Sable’s display showed a dark seal with no live image.

Someone had written the dead from Orison Gap on the bay’s inspection wall. One hundred forty-seven names occupied four columns. Charter crew appeared beside convoy riggers, pilots, and passengers. No rank marks separated them.

Kessa stopped at the final column.

Orra touched her shoulder once, not to steer her away. “We start when you can.”

“We started yesterday.” Kessa set Tomis’s brass torque key on the open bench. “This only decides whether we learned anything.”

The oldest captain in the bay folded his arms. His face came from an anchor beyond Brine, its transmission delayed by nearly a second. "We learned that a marshal will fire through civilians to preserve command."

A woman beside him answered from another display. "We learned that routebreakers can collapse a junction and call the result evidence."

"Tern had a hold active during the cut," Kessa said.

"We have your account."

"You have the part the Charter could not seize." She turned the torque key so its diagnostic contacts faced upward. "Now you get the part I kept because it belonged to my brother."

Pell connected the key to Mica Hand's bench with two obsolete leads and an adapter he had soldered during the approach. The first files appeared as dense machine traces from Lark-3, recorded twelve years before any of them had used the word veilback. The room recognized the format. Routekeepers had inherited the same error codes, the same narrow plots, and many of the same excuses.

Kessa opened the voice channel embedded beneath the torque calibration table.

Static filled the machine bay. Then Tomis spoke.

"Lark control, this is exterior apprentice Rho. Gradient load has crossed the west cage out of sequence. I have three beats on Stations Two, Three, and Five. Request cold shutdown and worker evacuation."

His voice sounded younger than Kessa remembered. Memory had given him her present age and a steadiness he had not yet earned. The recording returned the quick breath between shutdown and worker, the scrape of his glove on the suit microphone, and the effort required to sound useful while afraid.

Lark control ordered him to maintain position.

Tomis repeated the evacuation request. He named a false agreement among cage clocks. He reported movement after resonator correction. When control called it a calibration event, he invoked the worker stop in the same formal cadence Kessa had used at Nacre-9.

A second voice entered the log, machine-flat and without hesitation.

AUTOMATIC HOLD AUTHORITY ACCEPTED. LOCAL SAFETY STOPS SUSPENDED UNDER CORRIDOR CONTINUITY CLAUSE.

The trace on the bench rose across all nine stations. Tomis shouted for the exterior crews to cut their suit tethers and push clear. He did not tell them to reinforce the cage. He did not miss an assigned correction. His last complete order cleared the west spindle thirty-one seconds before stored geometry tore it across the service plane.

Kessa let the recording run through the impact alarms.

No one asked her to stop it. That restraint hurt more than pity would have.

At the final timestamp, a Charter diagnostic swept the file and replaced its event label. BIOLOGICAL RELEASE RESPONSE became OPERATOR-INDUCED OSCILLATION. The raw phrase survived only because the torque key's calibration cavity had copied the pre-review buffer before the change.

Pell enlarged the paired records. "Checksum on the original precedes the finding by forty-three minutes. The replacement checksum belongs to the inquiry bundle."

A captain near the coolant manifold leaned closer. "Can they claim corruption?"

"They can claim weather if they like," Pell said. "The cage clocks authenticate each other."

Kessa rested two fingers beside the key. "Tomis ordered evacuation. The automatic hold overrode him. The Charter report blamed him for failing to maintain the hold that killed him."

Across the bay, routekeepers looked toward the names on the inspection wall. Orison had made Halvek's command visible. Lark-3 made its age visible.

Orra called the room to order by striking a wrench once against the bench. "Motion before the chain crews: no union routekeeper will accept or execute a new hold command until the migration passage clears. Existing cages proceed to safe release under local worker authority. Discussion."

The objections came before the wrench stopped ringing.

A Brine captain had six million people dependent on food lifts that still crossed a fixed corridor. Another crew had families in a Charter dormitory whose air contract could be revoked. Tern's surviving station leader wanted every resonator cut immediately and dropped into the dust. A remote supervisor warned that refusal under corridor law carried prison terms for every person holding a cage key, not only captains.

Kessa listened until sabotage entered the room as a proposal.

"Blow the control receivers," the Tern survivor said. "All twelve. Halvek cannot send a hold to hardware that cannot hear him."

Several people voiced approval. Their anger had simple geometry: remove the part connected to the enemy.

"No," Kessa said.

The survivor rounded on her. Burns climbed from his collar into his jaw. "You stole your ship."

"I stole access. I did not blind my tools."

"Receivers gave him Tern."

"Overlap gave him Tern. We were cutting while his beam kept loading the core." Kessa pulled Anu's release sequence onto the largest display. Nine stations appeared around a dark center, grouped into three rings of action. "A dead receiver does not tell us whether a resonator has fully discharged. It does not

coordinate contraction waits. It does not warn a crew when the pulse trough moves. Symbolic damage gives us twelve different failures and no shared clock."

The man's burned jaw worked. "Then what are you asking?"

"Nine minutes of dark."

She expanded the sequence. The outer three resonators dimmed first. A contraction interval followed, measured through local loads rather than Charter geometry. The middle three released only after the juvenile settled against the reduced cage. The core triad shut during the pulse trough, when regrowth and outward motion reached their lowest measured conflict.

Kessa walked them through every manual interlock. No control beam could touch the cage during those nine minutes. No station accepted remote correction, timing sync, or corridor-priority command. Local clocks compared by light pulse and hardline. Exterior crews waited clear unless a mechanical latch failed. Cold-shear cutters remained ready but did not touch filament unless the topology refused to detach.

Orra cleared a tray of stripped valves from the bench and replaced it with a physical timing board. The routekeepers distrusted any plan that could not survive grease, delay, or a worker reading the wrong screen. She handed nine brass contact blocks around the room and assigned each to a resonator.

"We rehearse the failure, not the success," Orra said. "Outer crew, begin."

Three captains placed their blocks against the board. Pell started a local clock. At one minute twelve seconds, the first simulated station discharged. The second reported a residual load beyond the safe margin. The third captain moved her block anyway.

Kessa caught her wrist. "No majority rule in hardware. If one outer station carries load, all three wait."

"That spends the trough," the captain said.

"Then we spend it. A late safe opening costs a cycle. A mistimed opening costs a crew."

They reset. This time Orra introduced a false green signal from the Charter layer, then killed the hardline between two stations. The room argued over which clock retained authority. Kessa made them trace the light pulses by hand until they found the break between station time and ship time. A third run inserted a habitat tug inside the exclusion zone with four minutes remaining.

The Tern survivor wanted to continue. "We cannot surrender every window to a late civilian."

"We do not begin while a vessel remains inside the plane," Kessa said.

"And if Halvek places one there?"

"Neutral cutters remove it. If they cannot, we abort."

"We may get one chance."

"That does not improve a bad cut."

His stare held the remembered spindle, workers tumbling through geometry that every official display had called controlled. At last he put his contact block back on the tray.

Brine's captain requested the board. She ran the sequence with food-lift traffic still moving until the final minute, because her habitat could not empty its transfer schedule for a theory. Her first attempt trapped two lift tenders between the outer stations. On the second, she created a convoy lane along the cage axis and discovered the departing hollow would cross it. The third required stopping food movement twenty-two minutes before the dark began.

"That loses one substrate cycle," she said.

Marl Quade spoke from a small relay image beside Accord's green mark. "One cycle can be rationed. A broken transfer spine cannot."

"You do not operate our vats."

"No. I count who eats from them. Publish the loss and we will distribute it."

The captain erased the final lift from her board. She did not look relieved.

Next came prosecution. A station supervisor read the continuity clause aloud and listed what seizure would mean: air accounts frozen, family berths revoked, pensions attached, children denied route apprenticeship. The consequences had been written to make refusal feel private even when the danger crossed twelve systems.

Kessa put Tomis's key beside the timing board. "They used that clause to suspend his worker stop. Nobody at Lark faced the order together. The Charter separated each choice until obedience looked like maintenance."

"You can say that from an unregistered tug," the supervisor replied. "My children sleep in Charter spin."

"I can say only what I am risking. You name your own risk."

Orra opened a union register and turned it toward the room. "Every crew signs one declaration. Every family named by a signer receives shared berth priority on independent vessels. We cannot protect a pension. We can prevent the Charter from isolating households one at a time."

Captains began adding capacities beneath the declaration. Mica Hand offered thirty-two emergency bunks. A Brine tender offered nine. Two station boats offered air and acceleration couches but no long-duration food. The list remained inadequate, concrete, and larger than it had been ten minutes earlier.

Kessa ran the board a final time. No planted failure appeared. Outer contacts opened, followed by the contraction wait. Middle stations discharged against a falling load. During the modeled pulse trough, the core triad went dark. Pell stopped the clock at eight minutes fifty-one seconds.

"The nine-minute dark includes margin," Kessa said. "Use it. Nobody wins a prize for giving Halvek nine seconds back."

"What happens after the ninth minute?" the Brine captain asked.

"We see whether the hollow leaves safely."

"That is not a route plan."

"It is the only release we have tested without injury."

"You want us to discard six million people's corridor on a partial test."

Kessa kept her hands flat on the bench. "I want you to stop adding load to an animal already trying to leave. The corridor goes when it detaches. If you maintain the hold, it still goes, only through your station."

A captain transmitted from a mining system with a seven-second round trip. "How many anchors can you release together?"

"Three linked anchors on the first attempt. The pulse crosses them closely enough for one timing chain. We learn from those before scheduling the next group."

"And if one does not detach?"

"Then its local crew restores no hold. We read the load, protect nearby structures, and change only what the instruments support."

Orra watched the displays. "Halvek will attempt remote authority."

"The neutral cutters can sever his beam relays without firing on his ships," Kessa said. "If they consent."

"They have." Orra nodded toward three green marks beside the chain diagram. "Rescue neutrality includes preventing another forced load event where crews and habitats face immediate risk."

That interpretation would not survive a Charter court without scars. It might not survive the morning. Kessa saw the same calculation pass through the room. They could call their refusal safety law, mutiny, or maintenance discretion. Continuity carried enough beam power to define the practical term.

One of Threadbare's crew raised a hand from the rear bulkhead. Vasken had cleaned Orison blood from his suit but missed a dark seam at the wrist. "Chief, our transponder still accepts Charter seizure codes."

"It does."

"Then we can promise everybody nine minutes and lose our cutter the second their relay gets a clean angle."

Kessa looked at Orra. The routekeeper captain gave a small shrug that transferred the decision without making it easier.

"Strip it," Kessa said.

Vasken did not move. "The whole transponder?"

"The Charter board. Keep civilian collision identity and rescue beacon."

"That voids the tug registry."

"The registry already calls her evidence."

Behind him, Jori unlatched a tool roll. Two more crew members followed. No cheer moved through the bay. They left to do work that would close every lawful berth in the Reach to Threadbare.

The vote began station by station.

Each crew spoke its anchor name, declared control of local cage hardware, and accepted responsibility for refusing new holds. The words varied. Some captains invoked the union's worker-stop covenant. One called Halvek's commands unlawful after Tern. Another refused to use legal language at all and said her crew would not tighten a wound because a distant officer feared the road disappearing.

Brine delayed.

Its captain left the channel to speak with habitat councils and food-lift crews. While they waited, the machine bay grew warm with too many bodies. Orra passed cups of water drawn from a cutter already rationing its tanks. Kessa stood by the torque key and resisted closing Tomis's file.

Anu came beside her. "You said biology once in the meeting."

"I can remove it from the minutes."

"I was going to congratulate you on using it accurately."

"That sounds expensive."

Anu studied the frozen release diagram. "Three safe releases will prove a method. They will not prove every juvenile carries identical injury."

"I know."

"Say it when they start calling the sequence universal."

Kessa glanced toward the captains. "Will they still follow it?"

"If you say what it cannot promise, perhaps."

A clang carried through Mica Hand's hull. Then another. Across the collar, Vasken's team had opened Threadbare's transponder housing.

Sena sent Kessa an exterior camera view. Jori held the old Charter board in insulated tongs. Its status lights continued blinking impound red after disconnection. Vasken cut the data spine with a ceramic saw. The final light went out.

On every traffic display in the bay, Threadbare's registry icon vanished. A moment later Pell restored a plain civilian beacon under the tug's name, without license class, owner code, or authorized route field.

Orra lifted her cup toward it. "Ugliest free ship I have ever seen."

"She looked worse licensed."

Brine came back on channel.

Its captain appeared with three passenger delegates behind her. "Brine commits. We maintain essential lifts until the release window, evacuate the transfer spines, and refuse every new hold command. Our councils require open telemetry during the attempt."

"You will have it," Kessa said.

Ten anchor marks turned green.

The eleventh belonged to a station whose controller had spent the meeting warning about prosecution. He took off his Charter badge before speaking. "My crew commits under the worker stop. Families in the station dormitory have been moved aboard local craft. We ask the union to record that we acted together."

Orra entered the declaration into the public log. Eleven of twelve marks held green.

Sable remained gray.

Kessa called its operations channel. The connection acknowledged receipt and offered no voice. She sent Tomis's complete Lark-3 log, Anu's sequence, the Tern overlap reconstruction, and the hidden amplification model Halvek's analysts had allowed into the chain before withdrawing it. Every packet received an automatic checksum.

No person answered.

Orra tried the union emergency frequency. "Sable control, confirm worker authority. Your doubled hold puts every orbital structure inside the failure field. We need your local load trace."

The dark seal stayed fixed.

A thin line appeared beneath it: COMMAND ROUTING RESTRICTED BY CHARTER CONTINUITY ORDER.

Someone in the bay cursed. Kessa watched the Sable mark and pictured nine resonators drawing harder around a wounded juvenile while route workers waited for permission from a fleet three days away.

She opened a direct tool channel and sent three measured load pulses into the silence.

For twelve seconds, nothing came back.

Then Sable's cage registered one broad contraction, strong enough to bend the timing grid across every display aboard Mica Hand.

Eleven crews had committed to open their anchors.

The twelfth was already pulling against its cage.

Chapter 18 — Nine Minutes of Dark

Kessa put her hand on the cold-shear trigger and waited for three anchors to disappear.

Orison Gap filled Threadbare's cupola in spare pieces: three black corridor mouths, nine stations around each hollow, a scattering of service craft holding beyond the exclusion planes. No planet backed the geometry. Without the anchors, little remained to mark the Gap except cold dust and the convoy's distant engine lights.

The nearest resonator wheel carried blue work lamps. The middle wheel showed amber. Far anchor's crew had chosen white. Those colors belonged to workers, not Charter control. For the next nine minutes, they would provide the only common reference allowed in the system.

Sena held Threadbare nose-in to the middle cage. Manual brass controls surrounded her wrists. The tug's damaged grapple drum remained locked after Orison's battle, leaving one good line and the illicit cutter mounted below the forward rail. Kessa sat beside her in an exterior suit with helmet open and Tomis's torque key clipped to her chest.

Behind them, eighteen crew waited at workstations or in the lock. Jori occupied the outer rail beside the cutter carriage, visible through Kessa's wrist feed. Vasken and two riggers held the emergency crank inside the forward fairing. Pell watched local clocks isolated from every Charter timing source. Anu covered the filament loads from a bench built for ship salvage, not animal stress.

Nineteen had crossed from Nacre. Kessa counted them before every dangerous job, even when she trusted the roster.

Orra Senn's voice came from Mica Hand, stationed between the near and middle anchors. "All local traffic clear. Habitat tugs confirm exclusion."

"Neutral screen?" Sena asked.

"Three cutters in position. No beam projection detected from Continuity."

"That means Halvek has discovered patience," Kessa said.

"No," Orra replied. "It means he has discovered range."

Continuity held beyond the dust line with six aligned cutters spread around it. Its nine control-beam emitters faced the linked cages. The cruiser could not reach them directly through the neutral screen without passing a relay beam along one of the cutters. Any such transmission would have to cross rescue jurisdiction first.

On Kessa's tool display, each anchor delivered a broad three-beat load. Near struck first. Middle followed four seconds later. Far answered after another five. The progression had tightened since Day 26. Anu had marked every interval and refused to call the change urgency.

"It indicates approach," she said now. "Do not assign intention to speed."

"Wouldn't dream of it."

"You assign intention to seized bolts."

"Bolts have motive."

Sena glanced toward Kessa. "Crew count complete?"

Kessa read the names. Every station answered. Jori finished last because his gloves covered the rail switch. His camera showed the middle cage's outer stations curving around darkness, their beams rendered as pale guides by his visor.

"Exterior ready," he said.

Kessa closed her helmet. Air sealed around her with a pressure tap. "Chain crews, declare local authority."

Near anchor answered first. Then middle. Far delayed through a final hardline check and joined them. Eleven routekeeper crews had refused Charter hold commands, but only these three would open tonight. If they failed, the other eight would inherit a method written in debris.

Pell started the shared clock.

At minus two minutes, public route telemetry froze. Traffic displays showed three corridors healthy and available, a deliberate last lie preserved for later evidence. Each local crew copied its raw buffers into independent storage. The neutral cutters opened rescue channels and warned every ship that geometry would become uncharted.

Kessa called the abort conditions one last time. A crew could halt before opening its first outer station for any reason. After the outer set discharged, restoration required a local load review, never a command from Threadbare. Loss of voice traffic did not count as failure while hardline timing survived. Loss of both meant that anchor waited in its present state and every nearby vessel withdrew.

Near control repeated the conditions without alteration. Middle added its mechanical shutter warning. Far control named two service boats assigned to catch workers if a tether failed.

Accord of Dust sent a compact acknowledgement from Irian. The convoy commodore did not approve the cut or claim authority over it. She confirmed that every attached habitat had received the corridor warning and that no civilian captain expected a certified route after the attempt. The message ended with a mass plot showing seventy million tonnes held well outside the predicted shear field.

Sena studied it. "She has pointed all that mass somewhere else."

"She has pointed it nowhere," Kessa said. "That comes next."

A final request arrived from Jori on the rail. He wanted the cutter carriage released from its travel lock so he could reach its manual feed if software failed.

Kessa approved the first latch and denied the second, keeping the carriage captive to one steel tooth.

"You think it will jump?" Jori asked.

"I think every tool jumps after someone says it cannot."

He clipped the short work line to his harness. "Then we agree on the tool."

At minus ninety seconds, Halvek called.

His image appeared on the central pane without its Charter rank border. Someone aboard Continuity had routed him through civilian emergency protocol after Threadbare stripped its registry.

"Routebreaker Rho, the convoy has three major habitat groups dependent on these corridors," he said. "Your release removes all certified passage across Orison."

"The corridors will fail when the hollows leave. We can choose whether crews stand inside the failure."

"You have one partial release and one uncontrolled escape as evidence."

"We also have Tern."

"Tern argues against proceeding."

"Tern argues against combining a cut with your hold."

Halvek's gaze dropped, perhaps to the same clock. "Delay four hours. I will establish civilian clearance and withdraw control authority in a documented transfer."

Kessa checked his ship plot. Two aligned cutters had changed angle by less than a degree, enough to place a relay path between Continuity and far anchor.

"You are establishing a beam line," she said.

"I am preserving the option to prevent a cascade."

"Withdraw the cutters."

"I cannot surrender control of three intersystem corridors to an unauthorized mechanic."

"You already surrendered their condition to an animal you kept pinned for a century."

The phrase cost her. Anu looked up but did not correct it.

At minus thirty seconds, Orra cut Halvek's image from the timing pane. "Relay geometry confirmed. Neutral cutters moving to intercept."

Kessa rested both boots against the deck. "No one follows Charter time from here. Local pulse and light only."

The shared clock reached zero.

Twenty-seven resonator stations went dark to the network.

Their work lamps remained. Their cage outputs did not change yet. Public displays lost all three corridor mouths at once, replacing them with unverified black circles. Threadbare's star tracker dropped into manual mode. The tug shifted half a metre as Sena removed the last automatic correction.

Minute one began with the outer three stations at each anchor discharging.

Near anchor opened cleanly. Its blue lamps drew apart as the hollow's topology relaxed between them. Far reported a sticky power gate on Station Seven, then cleared it with a local hardline command.

Middle resisted.

Kessa felt the load through the cutter mount before Anu's trace showed it. One outer station had shed its field. The second followed. Station Eight remained active at nineteen percent and falling too slowly.

"Hold sequence," Kessa said. "Do not advance."

Across the lock camera, Jori braced beside the cutter carriage. "Eight's mechanical shutter did not seat. I can reach the manual dog."

"You stay on the rail."

"It will not discharge through software."

"Vasken, crank from inside."

The emergency crank turned. Station Eight's residual load dropped to sixteen percent, then stopped. The shutter status flickered between open and unknown.

Anu enlarged the filament response. "Contraction has begun at near and far. Middle still pushes against the active station."

The hollow showed no body. Its strain appeared as bent stars tightening around Station Eight and a white work lamp stretching into a curve.

Minute two.

A narrow beam flashed from one aligned cutter toward far anchor.

The neutral cutter Last Measure crossed it with a rescue foil extended. Light scattered across the foil in a green fan. Its captain broadcast the interruption on every channel. "Remote load control denied under immediate hazard authority."

Halvek ordered the cutter aside.

No one moved.

A second Charter relay fired toward near anchor. Mica Hand severed it by placing a graphite ballast plate in its path, then released the heated plate into open space. Orra's crew treated military geometry as a rigging problem and made it look almost ordinary.

Station Eight still held sixteen percent.

Jori unhooked his waist tether from the work rail.

Kessa saw the motion on his camera. "Negative. Reattach."

"The dog sits under the carriage."

"We abort middle."

"And leave its outer pair open with Eight holding?"

The question already carried its answer. Restoring the other two outer stations would compress the juvenile during contraction. Leaving them open while Eight held could twist the topology toward the station. They had rehearsed an incomplete discharge, but not a shutter frozen in this exact position.

Jori clipped a short line to the cutter carriage and pulled himself beneath it.

Kessa released her couch straps. "Sena, take the rail."

"You cannot reach him before minute four."

"Then stop the clock."

"The animal does not use Pell's clock."

Jori's camera scraped along metal. The shutter dog appeared beyond the carriage, a recessed lever trembling under field load. Frost broke from it in curved flakes.

"Chief," he said, "I have worked this drum for nine years. Let me touch my own bad repair."

Kessa knew that repair. Jori had replaced the shutter actuator at Brine with a cargo-door servo after Charter supply refused their requisition. She had inspected it, signed it, and praised the adaptation. The servo remained sound. The old mechanical dog had bent under Orison's firing loads.

"Short line stays clipped," she said. "One attempt. If it does not move, clear."

"Understood."

At minute two forty-one, Jori put both boots against the carriage and hauled on the dog.

It moved six centimetres. Station Eight's load fell through ten percent.

The middle hollow contracted.

Space around the cutter rail shortened without moving any visible object. Jori's short line snapped tight. His body struck the underside of the carriage. The camera spun, showing stars, metal, then the white hook of Station Eight's lamp.

"Jori, report."

No answer came.

Vasken pulled the emergency crank. The dog seated. Residual load dropped to zero.

Kessa stared at the life trace beside Jori's name. A single red bar crossed it.

"Bring him in," she said.

Two riggers cycled through the outer lock. They could not interrupt the

sequence to retrieve him without leaving his body in changing geometry. They moved along the rail on independent tethers while Kessa kept her hand over the abort control.

Minute three.

All three hollows had entered contraction. Near and far settled within Anu's predicted range. Middle pulsed harder, injured by the delayed release but no longer pulled toward Station Eight.

"Continue to middle set," Anu said. Her voice had lost every trace of dry correction. "If we stop now, regrowth will load the open ring."

Kessa wanted a different answer from the instruments. They gave her falling strain, a narrowing safe interval, and Jori's flat trace moving toward the lock in his crewmates' hands.

"Middle crews proceed," she ordered.

Stations Two, Five, and Nine discharged at near anchor. The corresponding stations at middle followed five seconds late. Far lost hardline comparison for one beat and waited until its light clock confirmed the pulse.

Halvek's third relay attempt came from Continuity itself.

The cruiser projected a stronger beam between two neutral cutters, using their separation as a slot. It touched the edge of near anchor's cage and forced Station Two back to four percent output.

The juvenile recoiled. Blue lamps jumped across the plot.

"Sever it," Kessa said.

Last Measure fired no weapon. It rotated under full drive and dragged its drive plume through the beam path. Ionized exhaust broke the relay into useless flicker. The cutter lost one thruster cluster to feedback and began a slow tumble. Its sister ship left formation to catch it.

Six Charter cutters advanced.

Orra opened a direct channel to them. "Cross this line and you enter active rescue geometry. We will mark every beam source as a hazard to civilian recovery."

"Neutral cutters have interfered with lawful control," Halvek said.

"They have prevented a repeat of Tern."

At minute four, the aligned cutters stopped. Their crews had watched Orison's certified toll reach 147 over the four days since they declared neutral rescue status. None fired through the exclusion plane.

Inside Threadbare's forward lock, the inner hatch opened. Vasken and the riggers brought Jori in on a work sling. A crescent fracture crossed his visor. His suit had maintained pressure. Geometry had taken him through the carriage faster than the shell could distribute.

Kessa did not leave her station.

Pell removed Jori's channel from the active roster and moved his name into the sealed work log. Eighteen crew answered the next count.

Minute five brought the contraction wait.

No station changed state. That inactivity required more discipline than cutting. Near hollow's loads fell in an orderly slope. Far showed a brief inward surge as filaments closed around old resonator scars. Middle carried the delayed injury as an uneven oscillation between Stations Eight and Three.

Anu placed markers at each low point. "Their troughs are separating."

"How far?"

"Near enters first. Middle follows eleven seconds later. Far needs another eight."

"The chain plan allowed six."

"The chain plan did not include a jam."

Kessa looked at three local clocks. One command could no longer serve every anchor. If each crew acted on its own trough, their departing wakes might cross before the route between them cleared. If they waited for a shared low point, no such point might arrive.

"Sequence by observed pulse trough," she said. "Near first. Middle follows its own trace. Far does not anticipate."

The Tern survivor on far anchor asked, "What if near departure changes ours?"

"Then you read the changed load. Do not chase their timing."

Minute six.

Near anchor's topology pulled inward until its star arcs nearly touched. The juvenile had shed the outer and middle restraints. Only the core triad held the corridor throat open.

Pell counted the local beats. One. Two. Three.

The pulse trough opened.

Near crew cut its core triad.

Darkness changed posture. A broad lens shape folded away from the cage, compacted, then drew itself along a faint shear line toward middle anchor. No explosion followed. No station tore free. Blue work lamps kept their places while the corridor mouth ceased to exist between them.

Someone on the chain channel made a sound between a laugh and a sob.

"Hold voices," Kessa said. "Middle reading."

The first released hollow passed beyond local instruments. Its wake touched the middle cage as a shallow gradient. Anu recomputed the trough from the changed trace.

Minute seven.

Middle's juvenile pulled against the core triad. Station Eight's repaired shutter held open. Jori's camera feed remained black on the edge of Kessa's display until she closed it.

"Middle trough in four," Anu said. "Three. Two. Now."

Kessa pressed the cold-shear trigger.

The cutter did not cut tissue. Its command traveled by hardline to the three local stations, opening each field in a controlled fall. Core loads reached zero within half a second of one another.

For an instant, the hollow stayed.

Then its topology detached from the stations and contracted around an absence no human instrument could resolve. It followed the first wake. The bent white lamp at Station Eight snapped back into a straight point. Metal groaned through Threadbare as ordinary distance reclaimed the rail.

No alarms marked a lensquake.

Minute eight belonged to far anchor.

Its crew had no cold-shear cutter. They worked manual discharge boards while the Tern survivor called each falling load. The juvenile's pulse shifted when the first two hollows crossed ahead of it. Its trough arrived early.

"Core Three is not ready," far control said.

"Do not open the other two," Kessa replied.

"Pulse falling now."

"Wait for Three."

The captain swore at his hardware. A relay breaker had welded after the network dark. Two workers struck it with an insulated ram while the trace climbed out of the trough.

Halvek's forces held position. No fourth beam came.

Minute nine began.

Core Three opened. The next low interval lay twenty-one seconds ahead, beyond the public promise but within the safety margin Kessa had forced into rehearsal.

"Remain dark," she ordered. "Far crew owns the clock."

The nine-minute mark passed with no Charter control returning.

At nine minutes fourteen seconds, the pulse began to fall. Far crew released the other core stations together. Amber and white traces collapsed across the board. The last juvenile detached with a rolling gradient that tipped three service craft but left their trajectories recoverable.

Sena fired two short bursts and kept Threadbare clear of its wake.

Three hollows moved away from Orison Gap in sequence. Their compact

topologies appeared only through stars drawing close, separating, then drawing close again farther along the migration line. Behind them, twenty-seven resonator stations surrounded nothing.

Pell restored public telemetry. No fixed corridor returned. Traffic boards searched for registered anchor geometry and found open space.

Kessa unsealed her helmet. The cockpit air smelled of hot insulation and the medicinal sealant from the forward lock.

Anu tracked the released juveniles. "Their interval is shortening."

"How much?" Sena asked.

"The returning adult has increased its approach rate along the open path. Or our earlier model mistook resistance for distance."

"Deadline?" Kessa said.

Anu moved the projected arrival mark forward. "Sooner. I need the next pulse set before I give you a day."

On the work log, Jori's sealed name remained beside eight minutes fifty-one seconds, the rehearsal time he had helped them earn.

Kessa took Tomis's key from her chest and placed it by the manual controls. Outside, the three released hollows followed their shear thread into darkness. The gap they opened did not stay empty.

A much larger lens moved faster toward it.

Chapter 19 — The Convoy Turns

Irian ordered eleven kilometres of ship to turn toward a route that did not exist.

The command reached Accord of Dust's thrust control as a proposed vector, not an execution. Around the carrier, attached habitats and freight barges kept their old attitudes while tug clusters moved into new stations. The convoy had spent seventeen days learning how to survive a broken corridor. It had not learned how to rotate 70.4 million tonnes without giving any single engine enough leverage to tear the mass apart.

Irian stood in the logistics pit with both hands against the plot rail. Orison Gap's three fixed corridors had vanished from the board nine hours earlier. Their registered mouths remained as hollow circles because navigation software preferred a dead road to an empty field. Beyond them, three released juveniles drew faint shear wakes across uncharted space.

No one on the bridge called those wakes a route.

"Cluster Seven reports aligned," the thrust coordinator said. "Cluster Eight needs six more minutes. Hospital group requests one degree less roll."

"Give them half a degree and move the seed barges outward," Irian said.

"That increases the seed truss load."

"By two percent. The hospital cylinder loses surgical spin at the current rate."

The coordinator changed the proposal. Green arrows shifted around the convoy, each representing a tug, a connection point, and people responsible for a cable they could not see from the bridge.

Kindly Argument occupied a protected pocket beside Accord's second drum. Its surgeons had worked through Orison's 147 dead and the larger number injured. The cylinder carried patients who could not tolerate a long roll transient. Six seed barges on the opposite side carried no conscious passengers, only machine stock and crop cultures meant to feed settlements that no longer had fixed access to one another. Both mattered. Only one could report pain.

Irian reduced the hospital roll first.

Her maneuver board divided the turn into thirty-seven thrust intervals over four days. Each interval moved some portion of the convoy through a fraction of a degree. Tugs pulled habitat drums by their reinforced tow nodes. Barges coasted through larger arcs. Accord used its main drives only after the surrounding mass established a shared rotation.

If one cluster burned early, cables snapped. If a habitat lagged, its attached water bladders swung through neighboring traffic. If Irian waited for perfect synchronization, the released wake would decay before they learned where it led.

A warning opened over the old corridor marks. FIXED ROUTE SOLUTION

UNAVAILABLE. SEEK CHARTER GUIDANCE.

The bridge crew ignored it with practiced contempt.

Marl Quade came down the ladder into the pit carrying three manual navigation slates and a coil of physical voting tags. Condensation darkened the shoulders of his work jacket. Brine's passenger delegation had borrowed a cargo room near the water controls because no chamber aboard Accord could hold representatives from so many habitats.

"You started the turn," he said.

"I started tug positioning."

"People can feel tug positioning."

"They can feel the carrier preparing not to tear itself apart."

Marl put the slates on her rail. "Then tell them which direction their bodies are being prepared for."

Irian looked through the bridge windows. Engine lights marked a slow wheel around Accord. Beyond them, Threadbare held near the first released wake, taking measurements where charts displayed nothing useful.

"The juvenile path leads away from Sable's fixed approach," she said. "It gives us a moving gradient with lower fuel cost than open fusion transit."

"Lower does not mean available to every ship."

"No."

"How many fail the turn?"

"None, if the tug plan holds."

"That did not answer me."

Marl's strength as a delegate lived in refusing the comforting unit. A convoy could complete a maneuver while a habitat lost heat, a clinic lost spin, or a family decided that a local shelter offered better odds.

Irian opened the readiness table. "Forty-one modules can follow the wake at projected acceleration. Nineteen need shared tow. Seven cannot sustain the required thrust cycle without reducing spin or life-support load. Three of those can shelter at Orison service habitats. Four need repair or a crew transfer."

"And the people aboard them?"

"Seventy-eight thousand, total across the seven."

Marl read the names instead of the count. "Have they been told?"

"Their captains received the table."

"Their passengers did not elect those engines."

A thrust-status bar changed from amber to green. Cluster Eight had aligned. The first maneuver interval could begin as soon as Irian authorized it.

She left the command unsigned.

"Convene the passenger delegates," she said. "Captains too. We have forty minutes before the current geometry costs us the window."

"Forty minutes to consent to a four-day turn?"

"Forty minutes to tell me what authority I do not have."

Marl gathered the slates. "That may take longer."

"It usually does."

The cargo room had once held agricultural pumps. Their mounting brackets remained on the walls, each labeled for a Brine cylinder that might never receive it. Passenger delegates sat on folded crates or joined by local relay from habitats moving beyond easy boat range. Captains occupied the rear, an arrangement Marl had chosen to prevent rank from controlling who could see the working displays.

Irian entered without the commodore's white bridge jacket. She still wore its command collar. Symbols mattered less when denied badly.

Marl opened under the Free Convoy Articles. "This session does not certify the later crossing near the returning adult. We decide the immediate turn out of failed fixed-route geometry and the distribution of authority during that maneuver. Any ship may request shelter instead of following. No captain may treat staying as mutiny."

A habitat captain objected before he finished. "Individual refusal fractures tow geometry. My drum cannot detach from the carrier group without taking two water trains with it."

"Then describe that dependence to your passengers," Marl said. "Do not rename it command."

Irian projected the maneuver plan across the floor. The convoy appeared as mass and tension, each line colored by its least forgiving connection. She spoke in usable margins. Four days of thrust. A maximum roll loss of eleven percent in the outer drums. Fuel reserve falling to twenty-two percent if all seventy units followed. Higher cost for any late reversal. Shelter capacity at Orison limited by air, food, and radiation shielding.

"The released wakes do not remain fixed," she said. "We have measured their first direction, not their destination. Threadbare can track them. No certified chart supports the maneuver."

A delegate from an evacuation habitat raised her tag. "Does the wake lead to Brine?"

"No."

"Does it lead away from Sable?"

"Yes, on present observation."

"My family came from Sable. We were told the convoy would circle back when

the unrest settled.”

“That promise depended on fixed corridors.”

“Then who cancels it?”

Irian let the room hold the question. A commodore could cancel a destination under emergency authority. She had done so during fires, epidemics, and one reactor loss. This change carried no alternate port, only motion alongside an animal’s wake while the old network failed behind them.

“I can cancel an unsafe route,” she said. “I cannot choose what every ship considers survival. The maneuver needs coordinated thrust, but the destination decision must remain with each captain and passenger body under the Articles.”

A murmur moved across the relay panes. Captains did not enjoy hearing pieces of command separated in public.

Marl pointed to the first interval. “Who controls this burn?”

“Local tug masters control ignition within a shared window,” Irian said. “Habitat captains can abort their own tow. Accord holds the mass plot and publishes corrections.”

“Who decides which modules reduce spin?”

“The affected habitat and medical crew.”

“Who decides whether a noncompliant ship gets cut loose?”

Irian examined the tension web. Under naval practice, she would. Under convoy practice as she had used it until Brine, the answer still tended to arrive at her console.

“The neighboring tow group,” she said. “With a passenger delegate on the channel. Any cut order enters the public log before execution unless immediate collision prevents it.”

A freight captain laughed without humor. “By the time a committee agrees, my barge will be through someone’s drum.”

“Then immediate collision grants action. Convenience does not.”

The room worked through the turn one authority at a time. Fuel distribution moved to a council of tug masters because no bridge officer could see every engine’s condition. Berth transfer remained with receiving habitats. Medical triage stayed aboard Kindly Argument. Irian retained the right to call shared thrust windows and close any vector that endangered the full convoy.

What remained of central command grew narrower and more honest.

The seven weak modules demanded separate decisions.

Three captains requested Orison shelter. Their passenger delegates confirmed the choice after publishing air projections and the risks of isolation. They carried nineteen thousand people among them. No one applauded. Shelter meant staying beside dismantled anchors with local service habitats, limited industry, and no

guaranteed relief corridor.

Four modules chose repair and tow reassignment. One transferred children and intensive-care patients before the turn. Another unloaded a machine shop to reduce mass. A third surrendered half its water reserve to a stronger drum in exchange for shared thrust. The last required a replacement reactor feed that existed only on a seed barge.

The seed custodian refused at first. "If I strip that feed, we lose automated germination control."

A delegate asked, "Can people run it manually?"

"For how long?"

"How long do we need?"

The answer moved through agronomists, maintenance workers, and the Brine crews who had operated food-substrate vats without automation during strike years. They could cover one planting cycle by hand. The reactor feed changed owners.

Irian watched expertise flow around rank. Every concession slowed the plan. Each also removed a hidden assumption that would have failed under thrust.

At thirty-six minutes, Marl called for a procedural count. Passenger delegates authorized the immediate turn by a margin large enough to act, with three shelter groups abstaining because they no longer joined the maneuver. Captains accepted the distributed authority table. Several entered formal objections beside their acceptance.

"Objections remain visible," Marl said.

"So do cables," Irian replied. "Both help when they carry load."

She returned to the bridge with four minutes left in the initial window.

The logistics pit had changed the plan while she was gone. Tug masters annotated the thrust intervals in local language, with repair times and hand signals where network timing might fail. Accord's neat green arrows had become a thicket of smaller marks. Irian understood less of it at a glance and trusted more of its detail.

"Shelter groups separating," the thrust coordinator said. "They request supply release before Interval Three."

Irian opened the distributed stores. Brine had already divided food substrate among many ships. The sheltering habitats needed more than food. They needed water reclaim membranes, machine tools, radiation foil, medical cultures, and fuel cells capable of surviving a long quiet.

Every item removed from the convoy reduced its endurance. Every item withheld turned the right to stay into a sentence.

"Allocate six months at strict ration," she said. "One full repair shop. Two seed

libraries, not one. Include manual fabrication patterns.”

“Six months leaves us below the crossing reserve.”

“Recalculate across the reduced population and mass.”

“They chose shelter.”

“They did not choose abandonment.”

The coordinator changed the table. Supplies began moving by small tug before the larger rotation made transfer dangerous.

Interval One opened.

Irian placed her authorization beside the tug council’s signatures. Forty-one cluster leaders acknowledged. Nineteen shared-tow modules reported ready. The four repaired weak ships joined under reduced mass. Three shelter habitats held outside the web with their service craft clustered around them.

“Execute local burns,” she said.

Engine lights brightened in sequence.

Nothing dramatic happened. That reassured her more than spectacle could. The outer barges began slow arcs. Water trains tensioned their cables. Kindly Argument preserved surgical spin within half a degree. Across eleven kilometres, Accord’s truss accumulated load and passed it through braces designed to survive route entry, not a turn in open interstellar space.

The ship moved by fractions too small for the eye. Irian felt them through deck vibration and the changing work of her knees.

During Interval Two, a seed barge lagged six seconds. Its tow group aborted before the mismatch reached the truss. The public log showed the decision without requesting Irian’s permission. Tug masters shifted two craft, rewrote the local burn, and rejoined at the next window.

During Interval Four, a habitat reduced spin farther than planned to protect a cracked tow node. Its passengers floated for nineteen minutes. Their delegate filed the medical effects and kept the captain’s choice in force.

Interval Nine brought the first conflict the authority table could not settle neatly. A water train named Blue Remaining reported one tug losing coolant while its neighboring habitat demanded the train hold formation. The tug master wanted to drop the outer bladder. The habitat captain refused because that water covered eleven days of reserve for thirty-four thousand people.

Under the old command structure, both requests would have climbed to Irian. This time the tow group opened its local channel to a passenger delegate, a water technician, and the two nearest tug masters. Irian listened without taking control.

“The bladder survives a free coast,” the failing tug master said. “Mark it and recover after the turn.”

“It crosses Cluster Twelve’s arc in twenty minutes,” the coordinator replied from

Accord.

"Then Cluster Twelve shifts."

"That shift loads a hospital tow."

The water technician overlaid the bladder's internal baffles. "Do not drop the whole tank. Empty the forward third into the carrier line, then split the tow at the middle collar. Lower mass clears Twelve's arc."

"Transfer takes fourteen minutes," the habitat captain said.

"We own twenty-one before collision risk."

The passenger delegate asked the question Irian had trained bridge officers not to ask during a maneuver. "What fails if we wait?"

Answers arrived from each role. The tug might lose its pump in nine minutes, but a bypass could extend that margin. The habitat tow carried six percent spare tension. Cluster Twelve could delay one burn without losing the shared window. Kindly Argument would need advance warning before the resulting vibration reached its berth.

They chose the transfer. A maintenance worker bypassed the pump while water crossed through a flexible line into Accord's aft reserve. The bladder lost a third of its mass, the tow split at the collar, and two smaller tugs took its shortened train. Interval Nine ran seventeen minutes late.

No cable snapped. No captain surrendered command wholesale. Irian recorded which information had made the choice possible and left the decision under the tow group's names.

Her thrust coordinator exhaled after the final clearance. "We could have ruled in thirty seconds."

"We could have guessed in thirty seconds," Irian said.

"The next one may not give us twenty-one minutes."

"Then immediate authority still exists. This one gave us time, so we used it."

The coordinator looked at the repaired geometry. "It also gave us more work."

"Most survival does."

By the end of the first day, Accord had rotated seven degrees.

The old corridors remained off her port quarter, black rings around empty centers. Navigation software continued offering recovery burns toward them. Each suggestion assumed an anchor mouth that no longer existed.

Irian deleted the route package.

On the second day, the shelter groups received their last machine crates. A child's recorded message crossed to Accord, asking whether the carrier would come back after finding a road. The bridge did not answer on behalf of the child's family. Marl routed the question to their delegate, who promised only continued radio contact while distance allowed.

The convoy reached nineteen degrees.

Fuel use ran one point below Irian's worst case because local tug masters had found efficiencies the central model missed. Tow fatigue ran higher. Two drums reported bearing heat. A freight barge cracked an attachment collar and redistributed cargo without dropping from formation.

Threadbare moved ahead along the juvenile wakes. Kessa sent measured gradients instead of destination claims. The shear threads curved toward the threatened chain, not along any corridor humans had used. Sable lay near their projected course.

On the third day, Halvek transmitted a formal order to halt.

He offered one remaining fixed route beyond Orison, reachable through a costly reverse burn. Its cage still held. His message omitted the amplification model and described the three released hollows as an uncontrolled route loss.

Irian posted the order to every captain and passenger delegate. She attached current fuel costs without comment.

Reversing at once would consume twenty-nine percent of available reserve and place the convoy behind a cage known to fail harder under accumulated holds. Continuing along the wake cost eighteen percent under the current tug plan. The difference widened with every interval.

A captain asked Irian whether Halvek's route remained legally available.

"Legality does not add fuel," she said.

"Would you take it if the cost matched?"

She looked at the black corridor marks, then at the moving gradient from Threadbare. "I would ask what holds it open."

That answer entered the public log.

By Day 33's final shared burn, the convoy had rotated past forty degrees. Its main truss pointed along the wake. Barges and habitats occupied a stretched formation built for thrust rather than corridor compression. The weak modules held. The shelter groups dwindled behind them among Orison's dead stations, supplied but alone.

The maneuver board displayed a new line across Accord's projected path. Navigation marked it the point of no return because ships preferred an old phrase to a long equation. Beyond that line, returning to Halvek's fixed route required more fuel than continuing into uncharted space.

Irian sent the calculation to Marl, the captains, and every local tug master. Acknowledgements arrived in no fixed order.

"Interval Thirty," the thrust coordinator said. "All groups ready."

Irian did not make a speech. "Publish and execute."

Engines lit around seventy million tonnes of inhabited machinery. Accord of Dust

gathered the pull through its truss and crossed the line one slow metre at a time.
The recovery vectors behind them turned red.

Chapter 20 — The Hollowing of Sable

Sable's orbital ring broke seventeen minutes before Threadbare reached it.

Kessa watched the first fracture arrive as light, not telemetry. A white segment above the planet bent upward where no ring plane should have allowed it, remained there for three breaths, then divided into two images. One copy showed the segment intact. The other showed it folding through the elevator web.

Sena killed the approach burn.

Everyone aboard the tug leaned into restraints as thrust ended. Sable filled the cupola, a high-gravity world wrapped in cloud and industrial haze. Surface cities burned in night-side grids. They remained level, bright, and alive. Above them, the orbital works had lost every dependable direction.

"Station clocks disagree by eight seconds," Pell said.

"Throw them out," Kessa replied. "Use our pulses."

Threadbare sent a radar burst toward the nearest ring sector. Three returns came back. The first followed ordinary distance. The second arrived late from a segment their eyes placed farther east. The third described metal already passing below them.

Sena rolled the tug hard.

A ring truss crossed their old path with no warning from the traffic plot. It had once carried an elevator receiving station, cargo rails, and housing for four thousand workers. Now one end turned toward Sable while the other climbed. Shattered radiators dragged behind it like pale scales.

Kessa found the fracture point by load instead of sight. The broken truss pulled nearby debris into a curved stream. Every fragment accelerated along a local gradient left by the cage failure.

"Mark what moves together," she said. "Ignore where the cameras put it."

Pell rebuilt the plot around shared acceleration. False images faded to outlines. Real objects gained thick white vectors. A habitat drum spun near the ring's inner edge with one bearing gone. Two elevator cables had wrapped around its axis. An emergency beacon repeated from three apparent positions.

Anu sat at the ecology bench with both hands locked beneath its rail. "The juvenile detached. Severe asymmetry. It crossed through the ring plane six minutes ago."

"Where now?"

"I have several answers."

"Give Sena the one that can hit us."

Anu sent a broad hazard cone across the plot. It cut between Threadbare and

the damaged habitat.

Sable control transmitted a systemwide evacuation order. Half its sentences overlapped themselves. One version directed craft to the outer rescue orbit. Another placed that orbit through the falling ring segment. Kessa muted both.

"Habitat beacon first," she said. "Then the elevator cars."

Sena did not ask which elevator cars. Hundreds showed on the broken web. Some still climbed along cables whose upper stations no longer occupied a stable orbit. Others had stopped and become small sealed rooms suspended above a planet.

They approached the drum from below its rotation plane. Threadbare's one working grapple could not arrest the full spin. Kessa assigned three local tugs to pull against separate tow nodes while Sena matched the damaged bearing's wobble.

No shared camera agreed on the node positions.

Kessa went outside.

Sable's gravity pulled through her suit with more insistence than any deep-space job. The ring had turned workers' weight into spin; outside it, every loose tool preferred the planet. She clipped to Threadbare's forward rail and crawled toward the grapple housing while stars split around the departing juvenile's wake.

Vasken fed the line. His voice remained flat after Jori's death, each word stripped to work.

"Drum node crossing in eleven."

"Whose eleven?"

"Ours."

"Keep it that way."

The habitat rolled into view. Its skin carried Brine algae paint beneath fresh evacuation markings. A window band showed darkness across most decks. One lit compartment flashed a hand lamp in repeated pairs.

Kessa aimed the grapple at the node's acceleration path, not its visible image. Sena gave her half a metre of correction. She fired.

The tooth vanished through a delayed picture of the drum. For one sick instant it seemed to miss. Then the line took load eight degrees to the left and pulled Kessa against the rail.

"Contact," Vasken said.

"Local tugs, take your thirds."

Three lines tightened around the habitat. Its spin slowed unevenly. The elevator cables wound around its axis began to pull taut, connecting the drum to a broken ring segment below. If they reached full load, they would either cut through the

habitat or drag the rescue formation toward Sable.

Kessa moved the cold-shear cutter off its carriage. The tool had opened a juvenile cage four days earlier. Now she set it against human cable.

"People in the cars?" she asked.

Pell tracked pressure beacons along the wrapped lines. "Four cars. Two hundred sixteen registered passengers. The lowest car still has independent brake contact."

"Can it transfer to the surface line?"

"Sable ground control says yes. Their picture is twelve seconds old."

A voice broke onto the channel from the lowest car. "We have visual on the junction. Cable Seven remains attached below us. Cut above Car Four and we can descend."

Kessa found Car Four as a moving load signature. "What about the other three?"

No answer came for two seconds. Then a rescue controller said, "Cars One through Three lost pressure during ring fracture."

The number of living choices narrowed.

Kessa anchored the cutter above Car Four. "Ground control, take brake authority locally. No ring timing."

"Confirmed."

"Car Four, prepare for a hard catch."

A woman inside answered, "We have children out of restraints."

"Put them in any closed bunk and fill the spaces with clothing. You have ninety seconds."

The habitat drum rolled overhead. Kessa watched its grapple load climb while the three tugs fought to hold alignment. A second ring fragment entered the hazard plot, two minutes away by shared acceleration and twenty seconds away by one camera.

Sena trusted the load plot. "Fragment passes behind us."

"Unless the wake changes."

"Everything passes somewhere unless the wake changes." Her tone held no humor. "Cut when they are tied."

Car Four confirmed.

Kessa closed the cold-shear jaws around three elevator cables. These lines had carried ore, food, shift workers, and children between Sable's surface and orbital ring. Their designers had provided emergency separation bolts at the cars, not halfway through a web wrapped around a habitat.

She cut the first cable. Stored tension kicked the housing and sent a wave down the remaining two. The habitat shifted. One local tug lost its tow node and spun away trailing line.

Vasken reeled Threadbare's grapple to compensate.

The second cable parted cleanly.

A gravity pulse crossed the scene before Kessa touched the third. Stars lurched. Her suit altimeter gained six kilometres, lost nine, then blanked. The habitat's delayed image swept through her body while the physical drum remained above.

"Kessa, cut now," Sena said.

She drove the jaws closed.

The third cable separated. The wrapped upper web sprang away from the habitat. Car Four dropped along Cable Seven toward the surface junction, brakes firing in bright red bursts. Its beacon descended inside the atmosphere corridor and stayed pressurized.

The three dead cars fell with the severed upper lines.

Kessa had no tool that could change that fact.

The habitat's spin slowed enough for docking boats to reach it. Pressure counts arrived compartment by compartment. Two thousand nine hundred people remained aboard. Sixty-three needed immediate care. Eleven had died during bearing failure, already part of Sable's growing total.

"Hand rescue to local tugs," Kessa said. "Next load."

She stayed outside for four hours.

The next call came from Ring Clinic Twelve, a pressure ward mounted across two truss bays near the damaged inner rail. Its medical drum had survived the first fracture. Its docking neck had not. Eighty-one patients, fourteen staff, and three visitors occupied a cylinder whose only exit now opened onto six metres of vacuum.

The clinic's reserve tug remained attached by one tow node, but every burn rolled the ward toward a severed elevator cable. Sable control wanted the tug to hold position until a rescue shell arrived. The shell's cameras placed the clinic in three locations and chose the brightest.

Kessa rejected the feed. "Clinic, strike your hull from inside."

A medic answered, "With what?"

"Anything heavy enough to travel through the frame. Three blows, pause, one."

The first pattern came through Threadbare's contact microphone after fourteen seconds. Kessa put the sound against the raw radar returns. One return vibrated. The other two remained perfect ghosts.

"Mark the noisy one," she said.

Sena brought the tug beneath it while Mica Hand ranged from above. The clinic appeared to slide through Sable's clouded horizon, but its acceleration matched the damaged truss beside it. Kessa fired a grapple into the surviving dock collar and felt ninety-eight living bodies enter the drum.

"Load shared," Vasken reported. "Clinic tug still carries sixty percent."

The rescue shell approached on Kessa's corrected mark. Its pilot saw empty stars until the shell crossed the delayed image and nearly struck the clinic's radiator.

"Break right," Sena called.

The shell fired. One side of its plume entered a folded gradient and pushed less than the other. It began to spin.

Kessa paid out grapple line so Threadbare did not pull the clinic after it. Mica Hand cast a second line across the rescue shell's tail and stopped the rotation. For several seconds the three craft held one another without sharing the same visible sky.

The clinic director sent a patient priority list. Nine required powered beds. Twenty-three could move in pressure sacks. Four had open surgical fields protected by local tents. The remaining patients could cross in suits if the gap gained a rail and enough time.

Time offered neither.

A broken ring segment behind the clinic had begun accelerating along the juvenile's wake. At current load it would cross the ward's local position in eleven minutes. Sable control predicted twenty. The hull strikes and grapple tension agreed with eleven.

"We take the powered beds first," Kessa said.

The director refused. "Their couplers cannot pass the damaged neck. Cutting the bed frames takes eight minutes."

"Move the people without the frames."

"Two die if power drops."

Anu entered from the tug. "Route portable cells through suit umbilicals. The clinic spine uses standard forty-eight volt medical bus."

A biomedical technician objected that no suit lead carried certified isolation for an implanted pump.

Kessa looked at the crossing fragment. "Certification arrives after contact."

The technician built two leads from monitor cables, tested each against a water load, and wrapped the exposed junctions in pressure tape. The first powered patient crossed the vacuum gap inside a rigid sack while a medic hand-carried the cell. The second followed on a makeshift rail fired between the open clinic neck and the rescue shell.

Every transfer changed the clinic's balance. As people left, the empty ward became harder to hold. Fluid tanks sloshed inside their restraints. A surgical centrifuge kept turning after its room had emptied, pulling the truss off-axis.

"Kill the centrifuge," Kessa said.

"Brake control lost."

"Can you vent its flywheel?"

The clinic engineer found a mechanical dump behind a wall panel. Opening it would release fragments into the ward's service bay.

"Bay clear?"

"One technician."

"Move her."

The technician had gone back for the controlled-drug case. The director ordered her out. She argued that pain stock for ninety-eight people would be lost with the ward. Kessa listened to thirty seconds disappear.

"Take two days of doses," she said. "Leave the cabinet."

The technician filled a pressure pouch and cleared the bay. The engineer dumped the flywheel. Ceramic fragments crossed the empty service space and buried themselves in insulation. The clinic's roll slowed enough for the transfer rail to hold alignment.

Pressure sacks came next. Then suited walkers. One visitor refused to leave because his daughter remained under a surgical tent. Staff moved him with the tent team so the argument did not consume another crossing. The last medic carried the clinic register inside her suit rather than trusting a network that kept correcting people into false positions.

"Ward clear," the director reported.

The ring fragment reached six minutes.

Kessa checked the clinic tug. Its crew had stayed attached through every transfer. "Release your tow and come across."

The pilot said, "If we release, the empty ward rolls into the shell."

Sena laid a burn along the tug's local acceleration. "Push at three degrees below your apparent horizon. One second only. Then cut free."

"That points at Sable."

"Your camera points at Sable. Your load does not."

The pilot trusted her. The tug burned, the clinic moved aside, and both tow bolts fired. Threadbare reeled its grapple while Mica Hand pulled the rescue shell outward. The abandoned ward crossed behind them just as the fragment entered its volume.

Metal met metal without a visible collision. One image passed through untouched. The physical clinic folded around the fragment and shed its pressure shell in bright panels.

Ninety-eight beacons remained aboard the rescue shell.

Kessa recorded the lost ward under salvage abandoned after evacuation. The

designation preserved the order of events: people first, hardware after. Sable's casualty system had already begun turning uncertain signals into categories. She made this one carry a verified count before moving to the next call.

Work lost any clean chapter of time. Threadbare pulled a machine shop away from the ring's broken inner rail. Mica Hand caught a tumbling fuel depot with two grapples and vented half its propellant before heat reached the tanks. Neutral cutters established corridors by repeated radar pulse, each craft publishing raw transit times instead of corrected positions.

Elevator cars descended where lower cables survived. Others transferred passengers into climbing rescue shells. Kessa crossed a snapped web line hand over hand to reach a car whose docking collar had bent shut. She and Vasken opened it with mechanical wedges while Sable dragged at their boots.

Inside, thirty-eight people shared air meant for twenty. A boy held a ceramic worker token in both fists and would not release it when the rescuers fitted his suit hood. Kessa clipped the token inside the hood so he could see it.

"Does the ring fall on the city?" he asked.

"Ground crews are moving the pieces they can."

"That is not no."

"No." Kessa checked his seal. "It is not no."

Sable's surface defense tugs pushed the largest fragments into ocean corridors or higher temporary orbits. Some debris entered the atmosphere over uninhabited industrial basins. White tracks crossed the clouds. Surface grids dimmed beneath them, then came back. The planet survived because worlds carried more mass than cages, rings, and human certainty.

The orbital habitats did not share that scale.

At the west transfer cluster, six cylinders had torn free. Four retained pressure. One opened along a maintenance seam and emptied before any tug could reach it. The sixth drifted inside the wounded juvenile's chaotic wake, appearing on instruments at positions separated by hundreds of kilometres.

Kessa refused camera lock and read its distress beacon through Doppler shift. Sena matched the acceleration pattern. They found the cylinder thirty kilometres below its brightest image.

Its spin had stopped. People floated behind the windows, moving hand over hand through emergency lights. A routekeeper tug remained attached to the cylinder's tail with engines dead.

"Route crew reports seven alive," Pell said. "They stayed to move the habitat clear of Cage Station Five."

"Why were they at the cage after the union refusal?" Vasken asked.

No one answered until the tug transmitted its work orders.

CHARTER CONTINUITY PRIORITY. MAINTAIN DOUBLED HOLD. LOCAL WORKER STOP SUSPENDED. STATION EVACUATION DEFERRED UNTIL CORRIDOR STABILITY.

Halvek's authorization code occupied the bottom of every page.

Kessa read the timestamps. Sable's operations chief had received the union declaration on Day 26. The chief had kept the cage crews at their posts under Charter order. They had loaded all nine stations beyond nominal limits while orbital evacuations waited for a stable corridor that never came.

"Seven alive," she said. "We get them."

Station Five's wreckage turned between Threadbare and the routekeeper tug. Its resonator bowl still carried a residual field. Each rotation pulled the dead tug sideways and released it again.

A direct grapple would cross the bowl's load path. Kessa used the remaining elevator cable wound around their rail. Vasken objected once because its cut strands could unzip under tension. She showed him the doubled splice she wanted, and they built it together.

Sena placed Threadbare above the wreckage. Kessa and Vasken paid the cable out until its weighted end curved around the resonator bowl. A local tug caught the end on the far side, creating a loose loop. When Station Five rotated, the loop guided its residual pull into both ships instead of the dead tug.

"Load coming," Kessa said.

The cable tightened. Cut strands lifted from the splice like silver hair. Threadbare's hull complained from lock to engine brace.

The routekeeper tug drifted free.

A rescue boat crossed the cleared path and docked with it. Seven suited workers emerged. Two could move without help. Five came on rigid stretchers.

Behind them, the cylinder's passengers transferred to local boats. The last person left twelve minutes before another lens pulse folded the empty structure in half.

Kessa watched it go without counting the machinery. Pell counted people.

The seven route workers refused evacuation to Kindly Argument until they knew what had happened to their station crew. Two had broken ribs. One carried a pressure burn across his neck where a suit collar had sealed late. Their shift lead, a woman named Esra Vale, kept asking for Station Five's work log between doses of pain control.

Kessa brought the log to the rescue boat herself.

Esra lay strapped to a rigid board beneath portable lamps. Sable's gravity reached them even in orbit, faint but persistent, pulling every loose line toward the planet. She read the final commands on Kessa's wrist display and stopped at the order extending doubled hold through local evacuation.

"We requested release twice," Esra said.

"The requests appear here."

"Operations told us Continuity had accepted responsibility."

Kessa enlarged the authorization chain. Halvek's code approved the general priority. Sable operations supplied the local order and the names of supervisors who kept the crews in place. Responsibility had traveled through enough hands for every person to claim they held only one small part.

"Did the chief survive?" Esra asked.

"Not Station Two."

"He had a son groundside."

Kessa gave her the family-liaison channel rather than a phrase intended to soften it. Esra pressed the display against her chest until a medic removed it for transfer.

The rescue boat descended to a surface freight terminal because orbital beds had filled. Threadbare escorted it through an elevator corridor cleared of falling cable. Kessa watched atmosphere turn the cupola edge blue. Below the cloud deck, industrial cities extended across dark plateaus. Power districts had separated themselves from the damaged elevator grid and kept hospitals, pumps, and shelters running.

No impossible tide lifted streets. Buildings did not leave their foundations. Sable's surface carried alarms, falling debris tracks, and the sudden loss of orbital industry, but the world endured beneath the local violence.

At the terminal, cargo halls received people instead of ore. Floor crews painted berth rectangles onto concrete. Water tanks meant for elevator counterweights fed field kitchens through temporary pipes. Families waited beneath assignment boards for names arriving from incomplete passenger lists.

Kessa crossed the loading apron in a high-gravity support harness to inspect the rescue boat's damaged collar. Every tool pulled hard at her belt. Surface workers had no time to recognize Threadbare's unregistered crew as mutineers. They passed her sealant, asked for measurements, and moved to the next hull.

A shelter coordinator caught her beside the collar. "Are you carrying more down?"

"As long as orbital control can give us a real vector."

"Current displacement planning uses 31,000. That includes everyone removed from ring housing and the elevator stations. If your manifest duplicates a transfer, mark it before landing."

Kessa checked Pell's roster. Six names appeared twice because a damaged habitat and a rescue tug had both claimed them. She corrected the entries and added the seven route workers under the rescue boat's actual berth.

The coordinator watched the count change by one digit. "People think this board tells them whether someone lived."

"What does it tell you?"

"How much air to move into this hall." She pointed toward the temporary pipes crossing the ceiling. "Living takes administration after rescue."

Kessa sent the corrected roster to Sable control. On the far side of the cargo hall, the boy with the ceramic worker token sat inside a painted rectangle with three adults. He still held the token against his suit hood. A meal worker handed him a cup and waited until high gravity stopped his arm from shaking.

Threadbare could remain on the surface for eleven minutes before its engines lost the orbital window. Kessa finished the collar patch in nine. As the tug climbed, she saw the first managed ring fragment enter atmosphere over an empty industrial basin. It burned orange across the clouds. The city grids below did not blink.

By the seventh hour, Sable control had one reliable orbital picture built from thousands of raw pings. The ring no longer formed a circle. Three long sections remained in managed orbit. Two had entered atmospheric disposal paths. Fragments surrounded the elevator web, most drifting away from surface corridors. Emergency shelters on the ground reported crowding but no city loss.

Thirty-one thousand people had been displaced from orbital structures. The number included families in surface terminals, workers aboard rescue craft, and patients packed into industrial bunkers. It did not turn them into cargo. It told water crews how many mouths arrived before the next filtration cycle.

The fatality register kept changing.

Kessa came inside when her suit joints stopped answering cleanly. Sena pushed a heated drink into her hands and returned to the manual plot. Anu had tracked the wounded juvenile through the entire rescue. Its wake cut a ragged course outward from Sable, crossing and recrossing itself as damaged topology tried to align with the migration pulse.

"It escaped," Anu said. "But the core filament load remains asymmetric. It cannot follow the others cleanly."

"Can we reach it?"

"Not without abandoning rescue range. The adult may reach it first."

Kessa looked at the bent path. The animal had left its cage. Freedom did not repair what the doubled hold had done.

Pell brought the final route-worker list to the cockpit. Eighty-four names. Some had died in the stations. Others died aboard tugs sent to maintain beam alignment while the ring began to twist. Every one had an acknowledged Charter order attached.

Tomis's death had taught Kessa to distrust a report that used error as a grave

marker. Sable supplied eighty-four new versions of the same work.

“Keep the orders with the names,” she said. “No separate evidence file.”

Pell nodded. “Casualty control wants our rescued count before they lock the register.”

They gave it.

Near the end of Day 33, Sable published the stabilized total: 2,406 dead. No estimate hid behind the figure. Search zones remained, but control had accounted for every occupied ring sector, elevator car, habitat, and rescue craft. The surface survived. Thirty-one thousand displaced people had berths or ground-shelter assignments, though many held only a floor marker and a ration code.

No one aboard Threadbare spoke when the total arrived.

A new drive signature appeared beyond the debris field.

Continuity approached under rescue lights with six Charter cutters behind it. The cruiser had taken three days to follow the convoy’s turn and the wounded wake. Its control beams stayed dark.

Sable traffic assigned it a holding vector above the broken eastern ring. Halvek accepted without claiming priority.

Kessa opened the casualty register on a public pane. She placed the eighty-four route workers first, each name linked to the doubled-hold order. Beneath them came the remaining 2,322 dead and the shelter distribution for the living. She attached the amplification model his office had suppressed.

“Send direct to Continuity,” she said.

Pell transmitted it.

The cruiser acknowledged receipt.

Through the cupola, Continuity crossed behind a ring segment twisted into an open arc. Its hull lights traced the broken metal for a moment, giving Halvek a view no corrected Charter plot could flatten. Below both, Sable’s surface cities continued burning in orderly grids.

The ring no longer closed around them.

Act 3

Chapter 21 — The Routekeepers Divide

Halvek read the dead into the navigation table one name at a time.

The bridge of Continuity had dimmed its main plot because Sable's damaged orbital ring kept throwing false mass into every solution. Beneath the red emergency lamps, the casualty list occupied the surface where Halvek had once displayed seventy-three reliable routes. He used his finger rather than voice control. Each touch opened a service record, a berth assignment, a recovery note when anyone had recovered enough to identify.

Aris Pell, resonator electrician, thirty-four. Ordered to Hold Station Six after the first gradient alarm.

Mera and Dol Tann, married riggers, fifty-one and forty-nine. Found inside an elevator-web junction they had kept powered for evacuation traffic.

Taren Ves, apprentice routekeeper, nineteen. Last transmission requested permission to abandon the core triad. Permission denied by Charter control twelve seconds before the lensquake.

The list continued past the edge of the table. Two thousand four hundred and six people had died in Sable's orbital structures. Thirty-one thousand had lost their homes above the planet, though the surface cities remained intact. Halvek had known both numbers before he entered the bridge. Numbers gave command a surface it could grip. Names passed through that surface.

Behind him, Commander Rusk waited without shifting his boots. Six loyal cutters held close formation around the cruiser. Three others, still claiming neutral rescue status, kept station near the broken ring. Their captains had sent a joint demand for Halvek's arrest and preservation of all command records.

"Marshal," Rusk said. "The outer rescue cordon reports another unauthorized tug entering Sable space."

"Routekeeper?"

"Mica Hand. Orra Senn has refused inspection."

Halvek closed Taren Ves's record. "Let her work."

Rusk's hesitation showed in the reflection above the table before it reached his voice. "That contradicts the containment order."

"Yes."

A warning pulsed at the plot's lower margin. The wounded hollow had left a wake through Sable's orbital plane, and every automated system still tried to render that wake as a defective corridor. Cargo drones followed the false line until local pilots cut their guidance. Rescue crews worked with hand signals and laser

ranges. The machinery kept attempting to restore an order that no longer existed.

Halvek opened the amplification model he had hidden on Day Twenty.

Its first page carried his private command seal. Charter analysts had shown how each forced hold stored lens stress across the twelve-anchor chain. The curve rose slowly through the early interventions, then steepened after Sable doubled its hold strength. At the time, he had called the projection incomplete. He had ordered distribution restricted until staged evacuations could begin. Sable had received enough of his plan to reinforce, not enough to understand what reinforcement would purchase.

A model could not kill anyone. Orders could.

He dragged the casualty list beside the projected curve. The two panes aligned by timestamp. Station Six had failed precisely inside the analysts' predicted band. The orbital ring twisted seven minutes later. Elevator cables crossed paths that their tension systems could not recognize. Habitats moved out of stable planes while controllers saw delayed images and issued corrections to positions already gone.

"Do you want the command record sealed?" Rusk asked.

"No."

"Three captains have requested direct access."

"Give it to them."

Rusk stepped closer. "All of it?"

Halvek looked up. Rusk had served under him during two famine escorts and the evacuation of Jellan Deep. He understood discipline as a tool for keeping frightened crews pointed toward the same work. What he did not understand, because Halvek had prevented the knowledge from reaching him, concerned the difference between a hard order and a concealed premise.

"All of it," Halvek said. "Including my restriction on the model."

The commander's face tightened. "That will fracture the cutters."

"They have already fractured."

Outside the forward ports, Sable filled half the view. Its cloud bands looked undisturbed. Above them, the orbital ring had become a broken silver line. Sections still carried power. Others drifted under tug control, separated by black gaps where thousands of homes and work bays had once completed the circumference.

Rusk lowered his voice. "We can still restore command here."

"Define restore."

"Seize Threadbare. Detain Senn and the other union captains. Put local cage control under Continuity. We have six cutters and the strongest movable hold in the Reach."

The proposal matched Halvek's own standing contingency. It had once seemed severe but coherent. Destroy Kessa Rho's tug if seizure failed. Reassert the holds at every cage still reachable. Force the civilian convoy toward shelter while fixed corridors remained. Arrest enough routekeepers to make refusal expensive.

He brought the contingency onto the table.

Six cutters appeared as blue marks. Continuity carried nine resonator control beams, each able to override a local station at military range. Threadbare had no armor. A concentrated cutter pass could split the old tug before Kessa brought her cold-shear tool near another cage. Loyal crews could occupy three anchor stations within a day.

Then the model extended beyond the tactical display.

With three more holds, predicted shear crossed the Tern failure by a factor of eleven. With six, uncertainty widened past the limits of every Charter instrument. Local control might preserve a corridor for hours. The adult return would reach the chain on Day Forty-two, and any surviving cages would release their stored geometry into inhabited space. Destroying Threadbare could preserve authority. It could not preserve the network.

Rusk watched the projection. "We do not know that Rho's plan will work on the adult."

"No."

"We do know what happens when routes close. You taught us that."

Halvek touched the famine-relief record without opening it. Eight hundred thirty thousand dead had followed a route closure forty years earlier. He still remembered cargo pallets waiting behind a silent anchor while field stations sent ration estimates down to hours. He had built his career around refusing that helplessness. Every promotion had widened the number of people whose survival he could convert into capacity, schedule, and protected throughput.

Yet the arithmetic now rejected his oldest answer. A route held through violence could not deliver relief after it tore apart the receiving orbit.

A call request flashed from Cutter Bound Meridian. Captain Eles Var had placed herself at the head of the six loyal ships. Halvek accepted.

Var's face appeared above the table, helmet clipped open, a shallow cut sealed along her jaw. "Marshal, the neutral cutters have targeted our relay vanes. They say any hold transmission constitutes an unlawful attack."

"They are correct about the effect."

Her eyes narrowed. "Are they correct about the law?"

"I no longer control that determination."

"You command the force."

"For the next few minutes, perhaps."

Rusk moved beside the display but said nothing. Var looked between them through the channel, reading what the bridge had not announced.

"Rho caused the first breach," she said. "Her people stole Charter property, broke cages, and put the convoy on an uncharted wake. We lost one hundred forty-seven at Orison because Mott shielded fugitives with civilian mass. If you yield now, every death becomes permission."

Halvek heard the attraction in that sequence. It arranged disaster into disobedience, disobedience into remedy. He had used similar lines in briefings because crews moved more cleanly when cause pointed toward a person.

"At Tern," he said, "my hold overlapped Rho's cut after she warned us the systems opposed each other. At Orison, I fired through a habitat exclusion cone. At Sable, my restricted model allowed reinforcement without the failure projection. Her violations do not remove mine."

Var went still. "Is this channel recorded?"

"Yes."

"Then suspend it and speak to me as the officer who pulled eighty-seven people from Orison wreckage."

"I am speaking to that officer."

Her mouth hardened. "Give me authority to take the three neutral cutters. We can disable them without fatalities. Then we recover Continuity's command reach before the union occupies the chain."

"No."

"You are permitting mutiny."

"I permitted something worse. I gave incomplete risk to people bound to obey."

Var cut the channel.

Within seconds, the six cutter marks changed formation. Patient Fire, Civic Burden, and Measured Force remained around Continuity. Bound Meridian, Quiet Mandate, and Civic Measure pulled outward, drives hot, their vectors pointed away from Sable and the approaching routekeeper craft. Rusk issued no pursuit order. Halvek had not granted him one.

The bridge hatch opened. Charter security entered in gray pressure armor, led by Lieutenant Cera Venn. She carried no drawn weapon. Her squad spread only far enough to cover the command pit.

"Marshal Enro," Venn said, "the neutral captains have transmitted a warrant claim under emergency rescue law. Commander Rusk has also released the restricted model to fleet channels. I need to know whether you intend to resist confinement."

Rusk faced Halvek. The command transfer rested with him if Halvek stepped down, unless the cutter captains rejected his legitimacy as well. Every path still

passed through somebody's willingness to follow.

"Not confinement," Halvek said. "A restricted bridge watch until civil authority can receive me. I retain technical access by request, no weapons authority, no detention authority, and no unilateral command channel."

Venn glanced at Rusk. "Who holds command?"

"No one exclusively," Halvek said.

"That is not an answer this bridge can execute."

"Then we will make one."

He opened the fleet command charter and removed his personal seal from the top tier. The system demanded a successor. Instead, he divided permissions. Rusk received ship safety and maneuver. The three neutral captains received rescue coordination. Local routekeepers received control over cage access. Convoy command received civilian-mass timing. Weapon release required two keys from different groups.

Red objections covered the table. Charter software considered divided authority a fault condition.

Halvek overrode the objections with the same emergency clause he had used to centralize control at Orison.

"Exclusive command relinquished," the bridge announced.

The words left the room altered. Security personnel shifted their stance. Two navigation officers removed Charter command pins from their collars and set them beside their consoles. Rusk kept his pin but moved from behind Halvek's chair to the ship-safety station.

A new call arrived from Mica Hand. Orra Senn appeared with Sable's broken ring behind her. Grease marked one temple. "Enro, your cruiser just opened its permissions tree to routekeeper certificates. Is that a trap?"

"No."

"Bad answer. Your traps usually come with documentation."

Halvek sent her the division order and the full amplification model. "Read both before bringing a tug near us."

Senn scanned the first lines. "Kessa needs a movable gradient source. The adult lens will cross the edge of the Reach in two days."

"I know."

"You knew several things."

"Yes."

Anger moved through her face without becoming performance. "My people at Sable followed your orders. Some kept the core powered while their families evacuated."

"The casualty list names them."

"A list does not know them."

"No."

Senn looked away, perhaps toward another display. "I'm not granting absolution because you found a clean verb for surrender."

"I did not request it."

"What are you requesting?"

"Access for your engineers to Continuity's resonator deck. Full hardware survey. No hold may fire without routekeeper authorization."

The bridge crew reacted more sharply to that than to his confinement. Continuity's beam architecture carried military protections older than several current treaties. Opening it exposed command encryption, range limits, and blind arcs to workers the Charter had recently ordered arrested.

Senn gave him a long look. "I'll send six people."

"Send twelve. We have nine projectors, and two lost calibration during the Sable quake."

"You're taking orders well."

"I have little practice."

"Learn quickly."

After the call ended, Lieutenant Venn approached with a restraint band. She did not raise it.

"Required?" Halvek asked.

"Not if Commander Rusk accepts responsibility for the watch."

Rusk nodded once. "He remains on this bridge or in assigned quarters. Every transmission copied. Every technical instruction advisory."

Venn clipped the band to Halvek's belt rather than his wrist. Its indicator lit amber. Restricted movement, recorded location, no physical humiliation. He found the restraint more difficult to bear for its professionalism.

Across the fleet plot, the six cutters finished choosing. Bound Meridian, Quiet Mandate, and Civic Measure formed a separate group under Captain Var. They declined the divided command and announced withdrawal to Charter-held space. Quiet Mandate requested escort for crew who refused Var's departure. Patient Fire, Civic Burden, and Measured Force stayed with Continuity but surrendered weapons authority under protest.

One of them, Cutter Patient Fire, transmitted a roster of divided crew. Twenty-two wanted reassignment to Var's group. Seventeen demanded neutral rescue status. The captain proposed sealing the weapons bay and carrying both factions until a civilian berth could receive them. Halvek had once punished a captain for less visible uncertainty. Now he approved the practical care in it, then

remembered approval no longer belonged to him. Rusk accepted the proposal and assigned two rescue observers to the cutter. No one called the arrangement unity. It merely kept armed shipmates from turning a disagreement into another casualty entry.

“Do we stop Var?” Rusk asked.

Halvek examined the vectors. Pursuit would pull rescue ships from Sable and turn a political fracture into another engagement. Var’s cutters carried enough fuel to reach a sheltered system. They also carried records. Nothing in Halvek’s new arrangement granted him the right to compel their consent merely because he disliked the direction of it.

“No pursuit,” he said, then corrected himself. “My advice: no pursuit.”

Rusk entered the decision under his own seal.

Routekeeper shuttles docked along Continuity’s port spine. Their crews arrived with tool cases, independent clocks, and obvious distrust. Charter engineers met them at the sealed resonator hatch. For one tight minute, neither group offered credentials.

Halvek left the command chair.

He crossed the bridge under Venn’s watch and placed his palm on the hardware release. The cruiser read his identity, then requested confirmation from a routekeeper certificate under the new permissions. Orra Senn’s engineer pressed a scarred diagnostic tag to the second plate.

Locks withdrew through the deck.

The resonator hatch opened on nine control trunks descending into the ship, each bright with status lamps. These projectors had enforced holds from Tern to Brine. They could also cast a shaped gradient without closing it around a juvenile, provided someone supplied geometry the military manuals never contemplated.

“Kill automatic acquisition,” Senn’s engineer said.

A Charter technician bristled. “That leaves beam pointing manual.”

“Yes.”

“Across forty thousand kilometres of moving lens?”

“If you want the machine to decide what counts as a target, go read Sable’s debris plot.”

Rusk looked to Halvek. Habit pulled every face toward him.

Halvek kept his hands at his sides. “Routekeeper authorization controls the resonators.”

The technician disabled automatic acquisition.

For the first time since Halvek had taken command of Continuity, the main bridge plot showed no protected corridor. Fourteen ship markers separated into raw local tracks. Three wakes crossed them without destination labels, while

damaged orbits blinked in the same uncorrected frame.

A tightbeam request arrived from Threadbare. Kessa Rho's tug remained hours away, crossing the wounded juvenile's chaotic wake toward Sable. Halvek asked Rusk for permission to answer. Rusk granted a monitored channel.

Kessa appeared against the tug's scratched cupola. Fatigue had narrowed her face. A sealed cut crossed one cheek. She did not greet him.

"Senn says your resonators are open," she said.

"They are under routekeeper control."

"And you?"

"Restricted bridge watch."

"That phrase can cover a large room."

"Lieutenant Venn can provide its dimensions."

Kessa's gaze shifted, taking in the security officer and Rusk at the ship-safety station. "Why call?"

Halvek brought up Continuity's beam envelope. Nine projectors could move together, independent of a fixed cage, while the cruiser supplied ranging and thermal capacity. No other ship could produce a gradient of comparable strength. Used as a hold, it might injure the approaching adult and multiply the disaster. Used differently, it might shape the animal's approach long enough to clear an orbital plane.

He transmitted the raw specifications without Charter locks.

"You asked for a way to unfasten the chain," Halvek said. "I kept giving you stronger fastenings."

Kessa studied the envelope. "This can move the gradient center."

"Thirty-two thousand kilometres from the cruiser at full coherence. Farther at reduced strength. Two projectors carry damaged calibration."

"Can you repair them?"

"My engineers can. Your routekeepers must certify the result."

The adult's predicted path crossed behind her image, a broad curve approaching the twelve released and wounded points of the wake map. Sable's juvenile drifted out of alignment. Brine lay beyond it. A fixed hold would turn that misalignment into stored violence. A movable beam might offer a slope the animal could follow without closing around it.

Kessa lifted her eyes. "If I use this, nobody fires on my tug."

"I lack authority to promise that alone."

Rusk leaned into channel range. "Continuity will not fire weapons on Threadbare. The three cutters remaining with us have accepted divided release."

"Var?" Kessa asked.

“Departed with three ships,” Rusk said.

She absorbed the loss without calling it victory. “Send Anu the projector heat limits. Send Sena your manual pointing lag. I want independent clocks on every trunk.”

The orders reached Halvek as repair work, which made them easier to carry and harder to evade. He forwarded each package. Routekeepers entered the resonator deck while Charter technicians opened housings no civilian had seen.

Kessa kept the channel open. “What do you want in exchange?”

There it stood, the logic he had taught everyone to expect. Capacity purchased obedience. Rescue purchased restored authority. A movable hold purchased some future claim on the routes.

“Nothing,” Halvek said. “Record the transfer as evidence.”

Her expression did not soften. Good. Trust rebuilt too quickly would only repeat the concealment under kinder language.

Outside, the first projector housing rotated away from Sable’s wounded orbit. Its targeting marks disappeared from the bridge. A routekeeper’s independent clock replaced them.

Halvek sent Kessa the final release key.

“Continuity carries the one movable hold strong enough to shape the adult’s approach,” he said. “Use it as something other than a cage.”

Chapter 22 — The Adult Under Glass

The stars began sliding before Threadbare's instruments admitted anything had arrived.

Kessa stood strapped into the forward cupola with one palm against the manual console. Elistor's familiar white point drew itself into a hook. Three dim stars beside it widened into paired arcs, then swept apart until the glass held an empty curve between them. No edge marked the intruding body. Its passage appeared only as a rearrangement of everything behind it.

Sena killed the tug's automatic tracker when it tried to correct for six directions at once. "Independent clocks agree within four hundredths."

"Cage references?" Kessa asked.

"Agree with each other and nobody else."

"Some habits survive catastrophe."

Anu occupied the second couch under a web of temporary leads. Filament samples from Nacre, Brine, and the dead route hung in three shielded tubes beside her. Each thread had tightened along the same axis. None pointed directly toward the moving lens. They followed the curved gradient that preceded it.

"Effective diameter crosses 40,000 kilometres," Anu said. "Likely larger if the weak outer topology sits below our clocks' resolution."

On the plot, the adult veilback had no single shape. Parallax gave them one bent field. Tug drift gave another. Heat instruments found nothing. Gravitational timing mapped a broad back crossing the Reach, then lost it whenever local wakes folded over the signal. Kessa could not look at the result without remembering dark cloth lifting beneath Nacre's stars.

The name had felt too generous when Sena coined it. Now it seemed too small.

"Pulse rising," Anu said.

Three measured loads entered Threadbare through every loose object at once.

The first pushed Kessa's boot soles into the deck restraints. The second made the cupola's old scratches brighten as starlight shifted inside them. The third passed through the tug without moving it and set Tomis's torque key trembling in its clipped socket.

Across the wake map, eleven juvenile traces answered at different strengths. The three safely released hollows followed the adult's curve with narrow, clean signals. Others strained inside cages or moved through damaged fields. Sable's wounded juvenile answered late and from the wrong side of the approaching trough.

Anu expanded that trace. "There. Again."

A ragged pulse arrived after the adult's third beat. Its outer topology spread

across Sable's broken orbital plane, then folded toward Brine. The juvenile had escaped the doubled hold, but the lensquake had left its gradient asymmetrical.

Sena brought Brine's projected orbit onto the cupola. The habitat swarm lay beyond the system's red dwarf, days away by ordinary thrust and alarmingly close in bent geometry. Six point two million people occupied those agricultural cylinders. Thousands more evacuees crowded temporary berths after Sable.

"If it follows the current line," Sena said, "the juvenile crosses Brine's orbital plane in eleven hours."

Anu shook her head. "Do not make following sound deliberate. Its injured topology keeps falling across the available gradient."

"Can the adult pull it clear?"

"Perhaps during a matched trough. Not while their pulses oppose."

Kessa studied the load paths. An injured rigger with one functioning arm did not need a command shouted from farther away. She needed a surface placed where leverage remained possible. The scale changed. The work did not.

A tightbeam from Continuity arrived with projector status. Seven of nine resonators had passed routekeeper calibration. One damaged trunk could operate below half strength. The last remained open on the deck, its focusing rings misaligned by the Sable quake. Orra Senn's crews had removed automatic acquisition from all nine.

Halvek appeared in an inset under Commander Rusk's channel authority. The amber mark of restricted bridge watch remained visible at his collar. "Cruiser can hold present relative position for ninety minutes before radiator limits require a roll."

Kessa disliked the verb. "You will not hold the animal."

"The ship can maintain position," Halvek said. "The beams will do what you authorize."

Anu leaned toward the channel. "We need a gradient slope no steeper than six parts in ten million across the juvenile's core. Any closed contour risks another injury contraction."

"Projector minimum exceeds that at normal coherence," Rusk said.

"Then make it less coherent," Kessa replied.

A Charter engineer spoke from the resonator deck. "Diffusion will heat the outer rings unevenly."

"Your heat table allows eight minutes."

"Seven minutes forty at current damage."

"Seven forty gives us two pulse troughs. Build me a slope that moves."

The engineer began objecting in capacities, then stopped when Halvek asked for a manual field sketch. Kessa transmitted her geometry. Three projectors would

spread a shallow gradient ahead of Sable's juvenile. Two more would move that slope sideways during the adult trough. No beams would cross behind the animal. Nothing would close.

Sena read the sketch and tapped one line. "You've placed Threadbare inside the ranging gap."

"Yes."

"Excellent. The old tug deserves a simple retirement."

"We need local clocks."

"We could also need them from farther away."

Kessa enlarged the blind region. The adult's lens warped signals coming from either side. Continuity could shape a field but could not measure its exact effect near the juvenile. Someone had to place instruments in the gap and call corrections faster than the distorted images came back.

Anu unfastened her couch web. "I am taking the sample rack aft."

"You are staying in the couch."

"The filaments provide our best local trough detector. Your hull blocks two axes here."

"Kess," Sena said, "choose which argument you want to lose first."

Kessa looked at Anu's thin face and the bruise yellowing beneath one eye from Sable salvage. She wanted to send the ecologist onto Continuity, keep Sena out of the ranging gap, and perform the approach alone. That familiar urge disguised control as care. Nineteen crew had already taught her the difference.

"Rack goes to the forward rail," she said. "Anu stays inside the pressure blister. Pell handles the exterior clocks. Nobody crosses the lensward side."

Sena turned Threadbare toward the adult.

Ordinary distance stopped behaving cleanly within minutes. Their drive pushed aft while Sable's ring appeared to move sideways. A rescue cutter crossed the cupola twice in two different positions, one current and one delayed by a folded light path. Sena ignored both images and flew from laser ranges to three routekeeper buoys.

The adult occupied more of the star field with every correction. Kessa's body insisted that something enormous approached the tug, though the instruments showed their relative line remaining stable. Darkness rose without surface. Bent stars traced a curve forty thousand kilometres long, then slipped over it like sparks around a shoulder.

No eye looked back. No intention entered the pulse. The animal's danger came from mass, motion, injury, and the human machinery embedded along its migration path.

A routekeeper buoy reached the adult's outer gradient ahead of them. Its

beacon split into four images, each reporting a different range. Sena tagged the earliest signal, rejected it after its clock ran backward, then chose the dimmest image because its timing still advanced. The buoy's casing appeared intact. Its tethered calibration masses did not. One mass climbed a curve no physical line connected to the buoy; another circled an absence for six seconds and shot outward with enough speed to puncture Threadbare if their paths crossed.

"Clear the calibration fan," Kessa said.

Sena rolled beneath the first mass. A grappling arm unlocked in the repair gallery, struck its travel stop, and stayed there under a load the tug's frame sensors could not locate. Kessa released the arm remotely before it tore the mounting plate. The old mechanism drifted away, valuable and harmless compared with the hole it might have opened.

Pell called from the forward blister. "Outer clocks have a nine-hundredth split across two metres."

"That is our local shear," Anu said. "Not instrument drift."

Kessa asked Pell to retract the rack by half a metre. The clock difference fell. She had him extend it again, slower. As the rack crossed the same invisible boundary, the split returned within one thousandth. They had found an edge of the adult's outer topology through a change shorter than Kessa's arm.

She marked it for Continuity. "Keep every beam center at least three local-shear widths outside this boundary."

The Charter engineer answered that his plot showed the boundary seven hundred kilometres away.

"Your plot receives folded light," Kessa said. "Mine is trying to pull Pell's bolts out."

Orra Senn broke into the engineering channel. "Use Rho's local mark. We can reconcile maps after nobody dies."

Continuity shifted its proposed line. The adjustment cost beam reach and forced the cruiser closer to the adult's wake. Halvek did not argue for the cleaner military geometry. Kessa noticed because two days earlier he would have built a doctrine around refusing.

Another three-beat pulse entered the buoy. Its surviving calibration mass changed orbit without thrust, settling along the curve toward the juvenile. The movement gave Kessa a natural slope to copy. She laid Continuity's proposed gradient beside it and reduced the artificial field until both curves differed by less than their clock uncertainty.

Only then did she authorize the closer approach.

"Juvenile trace," Anu said.

Sable's hollow appeared as a knotted absence below the adult's leading gradient. Its filament core measured only tens of metres, too small to see, but its

damaged topology bent a region thousands of kilometres wide. One side contracted normally. The other dragged through a wake scar left by the failed cage.

Three beats passed through the hull.

The adult's signal reached them first. The juvenile answered late again. Between both rhythms, local gradient rose sharply enough to pull a tool bin from its brackets in the repair gallery.

From the forward blister, Pell reported, "Clock Three just gained two tenths."

"Relative to what?" Kessa asked.

"Everything I trust."

"Throw it out. Use One, Two, and the torque key pickup."

"That key does not have a clock."

"It has a load cavity. Call the pulse edge from vibration."

Pell muttered something about family tools and scientific standards. A second later, Tomis's old key appeared as a crude line on Kessa's plot. It caught each load change without trying to classify it.

Continuity moved into projector range. The cruiser looked small against the lens, a hard white splinter carrying nine open housings along its spine. Three neutral cutters spread around it as independent ranging points. Routekeeper tugs occupied wider positions with beams dark.

Rusk requested authorization.

Kessa checked every line twice. No automatic lock. No rear closure. Diffusion below Anu's biological limit. A moving field center timed to local clocks rather than Charter cage solutions.

"Open Projectors Two, Four, and Seven at twelve percent," she said.

Light did not appear. The effect reached them as a slow change in the tug's grapple drums. Slack cables shifted against their guides. The wounded juvenile's trace flexed toward the artificial slope.

"Contraction beginning," Anu said. "Right side only. Reduce Four."

"Four to nine percent," Kessa called.

The command crossed distorted space. Continuity's confirmation arrived before the request appeared to have left Threadbare. Kessa ignored sequence on the visual channel and trusted the independent clocks.

Pell counted load by touch. "Slope moving. Half a degree spinward."

Sena matched the tug's drift to keep the blister in the ranging gap. Thrusters fired in clipped bursts. Each plume bent around the juvenile and painted a false curve across the cupola.

A warning showed rising projector heat.

“Adult pulse in twenty seconds,” Anu said. “Maybe eighteen. Outer sample is changing faster.”

Kessa watched three different trough predictions separate. Continuity used military timing. Anu used filament tension. Tomis’s key registered the physical load after it crossed their hull. None agreed closely enough for a blind sequence.

“Give me the damaged side,” Kessa told Pell.

He sent a magnified trace. The juvenile’s wake scar opened and closed like a bad repair under alternating strain. Its intact side responded to the adult. The wound delayed the other half, forcing the animal across its own gradient.

A stronger beam would move it sooner. Strength had shaped every Charter mistake.

“Shift the slope ahead by eight hundred kilometres,” she said. “Do not increase power.”

The resonator engineer answered. “At current coherence, the field will take forty seconds to establish.”

“Let it.”

“Brine intercept narrows if we wait.”

“Then narrow it.”

Halvek’s voice entered, stripped of command polish. “Execute Rho’s displacement at current power.”

Rusk confirmed under his own seal.

Projectors slewed. The artificial gradient moved across the juvenile’s path without wrapping behind it. For several seconds nothing changed. Brine’s danger line turned orange.

Then the hollow’s intact side followed.

Its damaged topology stretched. Kessa felt the change through the console as a drawn cable reaching load. She had one hand over the emergency beam cut. If the scar opened farther, she would drop every projector and accept the orbital intercept rather than repeat Tern.

“Wound gradient stable,” Anu said. “It can move this far.”

The adult pulse arrived.

First beat: the cupola stars folded into long white needles.

Second beat: every filament in Anu’s rack contracted toward the same invisible curve.

Third beat: the wounded juvenile tried to answer.

Its late signal crossed Continuity’s movable beam and steepened the slope. Projector heat jumped. Threadbare rolled without thruster input. Sena caught the rotation manually, but the forward blister moved toward the lensward side.

"Pell, get inside," Kessa said.

"Outer hatch cycling."

"Now."

"The clock rack is hard-mounted."

"Leave it."

A sharp load struck the forward rail. One of the three clocks vanished from the plot. The others showed the juvenile's topology folding toward the adult, too quickly on the intact side and not enough through the wound.

Anu gripped her harness. "Cut Projector Seven."

Kessa sent the order.

Nothing happened.

"Seven not responding," the resonator engineer said. "Control ring jammed at twelve percent."

Tern returned through Kessa's hands: hold opposing cut, trapped geometry, men and women inside a service spindle as light bent wrong. She pushed the memory back into procedure.

"Can you shutter locally?"

"Manual housing access takes six minutes."

They had less than one trough.

Sena pointed to Continuity's ship vector. "Move the projector instead."

The cruiser could not turn quickly, but it could roll. A rotation would sweep the jammed beam away from the juvenile before thermal cutoff.

"Rusk, roll Continuity nine degrees anti-spinward," Kessa said. "Keep Two and Four stabilized."

Halvek answered first. "That crosses our radiator shadow."

"Your radiators survive ninety seconds. The juvenile may not survive the beam."

Rusk called the maneuver. The cruiser's attitude jets fired.

Because of the lens, Continuity seemed to bend before it moved. Its long hull curved across the stars, straightened, then began the actual roll. Projector Seven's gradient slid off the hollow's wounded side. Two and Four fought to preserve the shallow slope.

The bridge channel filled with thermal warnings. One radiator bank shut down. The open resonator deck climbed above safe work temperature, forcing routekeepers into shielded alcoves.

"Pell?" Kessa called.

"Inside. Clock rack has entered a better profession."

A loose rail crossed the cupola, turning slowly toward the adult. No one tried to

retrieve it.

The juvenile's trace settled along the shifted gradient. Its damaged side remained distorted, but both halves now moved in the same direction. Brine's intercept line stopped narrowing.

Anu held up one hand. "Do not celebrate. Pulse match has not happened."

Kessa had no spare attention for celebration. Projector Four approached its diffusion limit. The cruiser's roll had shortened their useful slope. Adult and juvenile entered another trough, this one obscured by overlapping wakes.

"Filaments disagree," Anu said.

"Which sample do you trust?"

"None alone. Nacre closes first. Brine carries less scar. Dead-route tissue follows the adult but cannot show contraction."

"Build the average."

"That would invent a body that does not exist."

Kessa understood the objection. Averages had helped the Charter flatten nine differing stations into one green lie. "Then give each sample a vote and tell me when all three descend."

Anu recast the display. Three narrow traces moved independently. Nacre dropped. Brine followed. The dead-route filament held tension four seconds longer, then released.

"Now," Anu said.

Kessa moved the shallow slope toward the adult's wake.

Projectors Two and Four slewed in matched increments. The juvenile crossed the gradient without closure. Its intact topology lengthened first. The wounded side followed through a delayed curve, shedding a faint filament trace into the space behind it.

The adult answered with three loads.

For one breath, the juvenile remained late.

Then its first beat entered Threadbare inside the adult's first trough. The second aligned more closely. On the third, both load curves occupied the same rhythm.

Every loose cable in the tug lifted and settled together.

Anu stared at the plot. "Matched pulse. Still not language."

"No one asked it a question," Kessa said.

Sena checked Brine's plane. "Intercept clearing. Two thousand kilometres. Four. Eight."

The juvenile moved along the adult's gradient, not captured by it and not dragged through a closed field. As both lens bodies aligned, the bent stars between them opened into a narrow region of calmer geometry.

Kessa marked its edges. The safe corridor had no fixed throat. It traveled with the animals and would vanish when their pulses separated. Yet for several minutes, local clocks agreed. A vessel entering at the right angle could cross the wake without a cage.

Continuity cut its overheated projectors. The cruiser completed its roll with one radiator bank dark. Routekeeper tugs moved in to inspect the jammed housing. Nobody restored automatic acquisition.

Halvek requested channel access. Rusk granted it.

"Brine reports the orbital danger receding," Halvek said.

"Keep them moving people inward," Kessa replied. "This alignment may not hold."

"What do you call the corridor?"

She watched the calm region travel across the plot. Names had a way of turning temporary work into property. Routes invited schedules, claims, and the old confidence that somebody could make motion stand still.

"A trough," Anu said. "A temporary matched trough."

Kessa nodded. "Log exactly that."

The adult moved deeper into the Reach. Beside it, Sable's wounded juvenile held the same three-beat rhythm. Between their bending fields, the temporary corridor opened another six hundred kilometres, just wide enough for the first convoy sighting buoys to enter.

Chapter 23 — Seventy Million Voices

Irian opened the vote while three habitat captains were still arguing about whether the crossing existed.

The bridge of Accord of Dust had become a logistics pit in the literal sense. Two deck plates remained open where technicians had rerouted guidance trunks after Orison. Temporary fiber ran across the overhead in labeled loops. Every working surface carried a ship slate, a ration estimate, or a range plot of the moving trough beside the adult veilback.

No chart certified that trough. It had opened when the wounded Sable juvenile matched the adult's pulse, narrowed within minutes, and returned along a slightly different line on the next cycle. Kessa called it temporary geometry. Charter remnants called it an unlicensed corridor. Irian's navigators called it a crossing because four hundred ten thousand people needed a noun before they could decide whether to enter.

Marl Quade stood at the central table with the Free Convoy Articles displayed between them. "The Articles require separate captain and passenger-delegate consent for uncharted mass movement."

"They require informed consent," Irian said. "We do not have complete information."

"We have all the information anyone has."

"That sentence should frighten you."

"It does. Open the vote."

Irian looked across the carrier's plot. Accord and its attached habitats occupied a broad, ugly cluster along the adult's wake. Tugs had spent eight days turning 70.4 million tonnes away from fixed routes. Freight barges now sat at angles chosen by fuel margin rather than design. Water bladders rode between habitation drums. Seed vaults had been distributed across nineteen ships. Kindly Argument kept its hospital cylinder inside a guard of three slow tugs.

Each mark represented mass. Each mass contained decisions made by people who would live inside the consequences.

She opened a convoy-wide channel. "This is Commodore Irian Mott. Under the Free Convoy Articles, we will vote ship by ship on the proposed moving-shear crossing. Captains hold one operational vote per registered vessel. Passenger delegates hold votes by inhabited module. Neither side can compel the other. Refusal preserves berth, stores, and local shelter rights."

A status box demanded a destination. No destination lay on any certified route. Irian entered: BRINE-SIDE SHELTER ARC VIA MOVING TROUGH, CONDITIONAL.

The system rejected conditional as an invalid place.

She overrode the field.

Marl leaned closer to the microphone. "Published risk packet follows. Read it before voting. If your captain says there is no time, report that on the delegate channel. If a delegate prevents crew from stating a safety objection, report that too. Silence does not count as consent."

The packet left Accord in thirty-one compressed bursts.

It contained every loss estimate Irian's staff could defend. Crossing modules might encounter clock splits, unexpected shear, tug separation, and total guidance failure. The predicted severe-damage band ran from six to fourteen modules depending on trough width. Evacuation before entry could reduce deaths but not prevent material loss. No model promised every module would survive. No simulation covered an adult lens body interacting with 70.4 million tonnes of distributed infrastructure.

Irian had removed three reassuring phrases before release. Manageable risk hid who would manage it. Acceptable loss assigned consent to the speaker. Successful transit assumed an end none of them had reached.

Captain Veyr of Habitat Kestrel called first. "Commodore, you published hull loss but not projected deaths."

"Because berth transfer can move people out of the weakest modules before crossing. If every transfer completes, the median model gives between zero and three hundred deaths. The outer band reaches two thousand one hundred. If transfers fail, the model no longer deserves a number."

"You expect people to vote on that?"

"I expect them to vote on the danger we have, not one I can make polite."

Veyr's delegate entered the channel. "And if we refuse?"

"Local shelters at Sable's inner moon, Brine's far agricultural arc, and three powered freight shells. Twelve days of guaranteed convoy stores, then local allocation. Tugs will place each shelter group before the main crossing."

"Will you remain?"

"No."

The honesty cost her more than a command would have. A captain could order departure and call the abandoned unreasonable. Consent required Irian to tell people that she would leave after provisioning them.

Votes began arriving.

Each ship transmitted two marks, one from command and one from passengers. Green indicated consent. Amber requested amendment or delay. Red refused. Gray showed no quorum. The plot filled slowly, never as one verdict. Mica Shelter Three voted green from its captain and red from its delegate. Freight tug Low Arithmetic produced the reverse. A water train with no resident passengers submitted only a captain's mark and listed the six riders by name.

An amber request came from Spin Habitat Far Lantern, population nine thousand eighty-two. Its delegate, Osrice Vale, asked Irian to attend a public question period. She moved the channel onto the main display. Rows of evacuees filled an old recreation drum under half gravity, their feet hooked beneath floor straps while the habitat remained despun for truss inspection.

Vale had grease on both sleeves and a child asleep against his shoulder. "Our captain says Far Lantern crosses in the third mass cluster. Your packet gives risk by module class, not by our actual damage."

Irian called up the inspection. "Your forward truss lost two diagonal members at Orison. Temporary braces carry current spin load. Crossing load depends on local shear direction."

A woman near the camera raised her hand. "That means what?"

"It means the braces may carry a pull along the truss. A sideways gradient could buckle them."

"Can you put us where the pull goes along?"

"Not with certainty. The trough changes between pulses."

Another resident called from the rear. "Then detach the damaged end."

Captain Sol Varo entered from outside frame. "That end contains air processing for four districts."

"Move the processors."

"Forty hours of work. Our window arrives in nine."

Voices rose. Irian let the delay stretch until Vale restored order by asking residents to hold questions on their slates. No command phrasing could shorten a structural fact.

Vale read the next question. "If we vote no, do you separate us from the carrier before our truss inspection finishes?"

"No. A tug keeps you stabilized until the local shelter vector begins. The shelter course uses lower thrust than the crossing approach."

"Which tug?"

Irian checked the board. No tug had yet received that assignment. Naming one now would steal it from another refusal whose needs remained unknown.

"I cannot give you a hull name yet," she said. "The allocation follows the final refusal count."

"So your guarantee depends on a vote you do not have."

"Yes."

The child on Vale's shoulder woke and stared into the camera. "Do we get to vote?"

A nervous laugh moved through the drum.

Vale shifted the child higher. "Berth residents sixteen and older vote directly. Younger residents join household consultations. That part comes from our local compact."

The child frowned. "I'm eleven."

"Then make your household work harder," Marl said from beside Irian.

This time the laughter carried enough breath to release some pressure without making the danger small.

A rigger in the front row asked whether Kessa's moving trough had been tested with habitat mass. Irian answered no. A nurse asked whether Kindly Argument would remain close. Irian said hospital position still depended on its own captain-delegate agreement. Captain Varo described the braces without claiming they would hold. The public period lasted twenty-eight minutes.

Far Lantern submitted captain green and delegate amber. Vale attached two conditions: an exterior tug inspection before approach and live truss strain on every local sighting slate. Irian accepted both conditions into the crossing plan. Other damaged habitats copied the strain requirement, turning one ship's doubt into a convoy measure.

The first aggregate showed sixty-one percent consent among captains and forty-eight among delegates. Too low under the Articles. More troubling, six habitat drums reported unanimous votes cast within ninety seconds of receiving a twenty-page packet.

Marl saw them too. "Those are managed returns."

"Or frightened people voting quickly."

"Both can happen."

Irian called the six delegates privately. Four admitted their local captains had opened a public channel and asked for a show of hands before distributing individual risk slates. One had counted only household heads. The sixth had used an old evacuation roster that excluded children over sixteen despite their current berth status.

She invalidated all six returns.

A captain from Drum Elian appeared on her command channel, furious. "You asked for speed and now reject completed votes."

"I asked for consent."

"My people want to leave."

"Then let them say so under the Articles."

"We have nine hours before the next wide trough."

"You have forty minutes to conduct a ballot that includes every eligible berth."

"Who gave you authority to invalidate my ship?"

"The same Articles that limit mine."

Elian cut the channel. His vote reverted to gray.

Irian's operations chief, Leto Har, slid a fuel report across the table. "Every hour costs shelter placement margin. If the vote runs beyond two cycles, we cannot provision all refusals and still make Kessa's entry window."

"Then publish that."

"It will sound like coercion."

"It becomes coercion if we hide it."

Har added the deadline to the public packet. The new line moved several amber modules toward red. Others shifted green, not from confidence but from understanding that delay carried its own cost.

Across the bridge, the mass board kept updating. Food substrate: divided among twenty-seven carriers after Brine. Potable water: sufficient through the crossing and forty-three days beyond at current ration. Machine seed: nineteen caches, three in modules now rated too weak for entry. Fuel: enough for one large correction per tug cluster, not two. Hospital capacity: overloaded by Sable casualties.

Seventy million tonnes did not speak. It resisted motion, consumed fuel, stored food, spun air around families, and carried tools no isolated habitat could replace. The title on Irian's original convoy manifest had called it essential mass. She had once treated that phrase as permission to keep it together. Now every component had a constituency, and preservation might require division.

Marl touched the machine-seed line. "The three weak modules can move their caches before the vote closes."

"Transfer time?"

"Two hours if captains release the cargo arms."

"Crossing window begins in nine."

"Then we have time."

"We have time if nothing jams."

Marl gave her a flat look. "That describes every useful action since Nacre."

Irian ordered the transfers offered, not imposed. Two modules agreed. The third, agricultural carrier Sown Argument, refused because moving its seed vault would require stopping spin in a habitation section with two hundred injured passengers.

Its delegate, a woman named Pera Noll, came onto the public channel. "If we stay, does the seed stay with us?"

"Yes," Irian said.

"Even if the convoy needs it beyond the crossing?"

"You hold lawful possession."

Captain Har objected off microphone. Irian muted him.

Noll consulted voices outside camera range. "We refuse passage. We will take Brine far-arc shelter and keep the vault operational for local planting."

"Recorded."

The red mark from Sown Argument carried twelve hundred forty people and enough seed stock to restart six staple lines. It weakened the convoy beyond the crossing. It strengthened those who remained. Irian forced herself not to rename the outcome loss.

More refusals gathered around it.

Some came from Sable evacuees who had survived one lensquake and would not enter another moving field. Some came from maintenance crews who trusted Kessa's method but not their patched hulls. A Brine delegation chose local cylinders over another uprooting. Two freight crews split, with half transferring to shelters while the rest volunteered to fly empty cargo shells through the trough.

The refusal count passed eight thousand.

Irian assigned a separate board to shelter provisioning. People became berth blocks, water allotments, waste capacity, medicine classes, and tug minutes. She had spent years translating lives into logistics without believing the translation erased them. Today every conversion faced witnesses.

A delegate from Kindly Argument requested priority passage for the hospital cylinder. Its captain refused.

"We cannot stabilize surgery during the shear," Captain Nemi said. "If you put us inside the first cluster, every clock split reaches life support before we know whether the guidance works."

The hospital delegate answered, "If you put us last, injured people remain in the wake while tugs spend fuel ahead."

Irian let them argue. Her instinct supplied a clean order: hospital centerline, two tugs, early crossing. Yet the Articles did not exist to decorate her preferred solution.

Kessa joined from Threadbare when asked for technical evidence. She looked more comfortable discussing damaged machinery than hundreds of thousands of listeners.

"The first cluster sees the least mapped geometry," Kessa said. "The middle gets better sightings but more wake disturbance from mass ahead. Last cluster risks a narrowing trough. There is no safest position."

Nemi asked, "Where would you put the hospital?"

"Where its captain can keep life support and its delegates accept the timing."

"That is not engineering."

"It is the boundary of engineering."

After twelve minutes, Kindly Argument chose the front third, behind two empty

sighting barges and ahead of the heaviest habitat cluster. Both captain and delegate entered green.

Kessa remained on Irian's private channel. "I need independent sightings from the convoy. At least one node per tug cluster, clocks isolated from Accord."

"My bridge can fuse them."

"That creates one failure point."

"My bridge already coordinates thrust."

"Through fixed-route assumptions. The moving trough will distort your incoming picture. If every cluster waits for your correction, half will act on old geometry."

Irian disliked the proposal because it made tactical sense. "Who arbitrates conflicting sightings?"

"Nearest verified node. Others publish raw clock and range. No hidden smoothing."

"You are asking me to distribute helm authority before the vote authorizes movement."

"I am asking whether the crossing you offered can function."

On the bridge wall, Accord's navigation crown showed every attached module as a subordinate mass. That architecture had helped Irian turn the convoy after the routes failed. It had also pulled all meaningful correction through one place: her place.

"Draft the network," she said. "Do not activate until consent clears."

Kessa sent a simple pattern. Each tug cluster would choose a sighting ship. Manual navigation slates from the Tern breach would receive local clock, laser range, and neighboring thrust. Accord would publish mass timing but could not overwrite a cluster's immediate shear correction. Two adjacent nodes had to confirm any large vector change.

Marl read it over Irian's shoulder. "Delegates should see this before final returns."

"It concerns navigation."

"It concerns who can decide to move their ship after the crossing starts."

Irian added the distributed sighting architecture to the ballot packet.

The second returns came slower. Drum Elan completed individual voting and shifted from its earlier unanimous green to seventy-three percent consent. Its captain accepted the result without apology. Two gray ships reached quorum. One captain withdrew a green mark after discovering a cracked truss pin in the latest inspection.

At six hours before the predicted window, delegate consent crossed the required threshold. Captain consent followed nine minutes later.

No cheer rose on Accord's bridge. The refusal board had reached eleven

thousand three hundred. Transfer requests continued. Irian kept the ballot open for the final verified modules while tugs began moving shelter supplies.

Pera Noll sent a new request from Sown Argument. "We have eight hundred open berths after reorganizing spin. Offer them to other refusals."

"Your life support margin?"

"Thirty-eight days with convoy stores. Longer if Brine accepts our seed contribution."

Irian connected her with Marl's shelter team. The act changed refusal from scattered red marks into a local convoy of its own.

The count settled at twelve thousand people choosing local shelters.

Irian published the number beside the crossing approval. She also published what they would receive: food, water, medicine, machine tools, three tug escorts, and authority over the far-arc stores left with them. No captain could strip those allocations to improve crossing margin without a new vote.

Leto Har pointed to the fuel board. "Leaving three tugs means the heaviest cluster loses a correction reserve."

"Yes."

"Our published loss band assumes that reserve."

"Recompute."

The severe-damage band widened. Irian released the update before anyone could claim the vote had closed on better numbers. Four modules requested reconsideration. Three remained green. One moved red and joined the shelter group with two hundred eighteen people.

Marl watched the final tally lock. "Approved."

"Conditional on the trough opening within Kessa's biological limits."

"Still approved."

Irian opened the convoy-wide channel again. "The crossing has consent under the Articles. Twelve thousand people have refused passage and will receive local shelter provision. Published loss estimates remain in force. We do not promise every module will survive. We do promise no refusal will be punished by withdrawal of earned stores."

She waited for the transmission to clear every habitat. Signal delay across the stretched convoy turned one statement into dozens of local moments.

Next came the authority change.

Irian removed Accord's automatic helm priority from the guidance crown. The interface warned that convoy integrity could no longer be guaranteed. She accepted. Sighting nodes lit across tug clusters, hospital escorts, freight trains, and habitat pairs. Each carried one of the manual slates distributed after Tern. Raw clocks appeared without central correction.

Captain Har stood beside her. "We can take priority back if the network diverges."

"No. We can request confirmation like any other node."

"You are still commodore."

"For mass timing and common stores. Not for local sighting."

Irian entered Accord as Node Seventeen rather than command root. The bridge plot redrew itself. Lines that once converged on her carrier now linked ship to neighboring ship across the convoy's whole length.

The arrangement looked untidy, slower to read, and harder to command. It also survived when she blanked Accord's own sighting feed for a test. Nearby nodes carried the geometry around the missing place without waiting for permission.

Outside, tugs peeled twelve thousand people and their provisioned modules toward the Brine far arc. Ahead, the adult's bent field gathered the stars toward another temporary trough.

Irian took her hands off the centralized helm. Across seventy million tonnes of moving infrastructure, thirty-seven independent sighting nodes took the load.

Chapter 24 — The Shepherd Net

Kessa built the formation with cable on Threadbare's repair-gallery floor.

Nine short lengths represented Continuity's resonator beams. She tied each to a brass washer and arranged them around a grease mark for the adult veilback. Three black fasteners stood for the neutral rescue cutters. Routekeeper tugs received mismatched nuts from Sena's spares drawer. The convoy occupied half the deck as a coil of old power line too thick to bend sharply.

On the wall display, proper symbols kept sliding as the adult lens changed every reference. Cable stayed where Kessa put it.

"Your cruiser cannot sit there," Halvek said over the open planning channel.

His image came from Continuity's bridge under restricted watch. Commander Rusk occupied the command station behind him. Orra Senn and two Charter engineers stood at the resonator deck feed. Nobody on that ship spoke without a channel recorder visible.

Kessa shifted the washer by two finger widths. "Here?"

"Then the adult's leading gradient masks Cutters Two and Three."

"They are ranging points, not a firing line."

"A range point nobody can see cannot report position."

Sena crouched beside the floor model. "It can report local position to its neighbors."

Halvek studied that. His habits preferred every geometry readable from one command center. Irian had just surrendered centralized sighting for the convoy. The same correction had to reach the military ships.

"Cutters pair with routekeeper tugs," Kessa said. "Local clocks and direct laser. Continuity receives their reports but does not smooth them."

Rusk answered. "Accepted."

Halvek did not say under protest. He pointed to the adult's projected curve. "You still lack leverage on the far side. Nine beams can shape one moving gradient. They cannot shape two while the juveniles release."

Kessa laid three more cable ends beyond the grease mark. These represented cage projectors at Brine, Nacre, and the last inhabited anchor still holding a juvenile. Eleven of twelve routekeeper crews had committed to the release sequence. Sable's cage had already failed. Three hollows moved free. The rest would need outer stations opened, then the middle three. The core triad could release only in the pulse trough.

"Local projectors do not hold," Anu said from the workbench. "They create open slopes toward the adult's wake. If any contour closes around tissue, we cut every beam."

A Charter engineer asked, "How do we determine closure when the field folds our sensors?"

Anu held up the three filament tubes. "Contraction direction, independent clocks, and juvenile pulse delay."

"That gives inference, not certainty."

"Biology often does."

Kessa moved the Nacre cable. "The formation does not need certainty. It needs failure boundaries everyone can see."

She drew a circle around the adult with a graphite marker, then cut the circle open in three places. No ship could project across those gaps. If guidance turned into confinement, the gradient would leak away rather than tighten. The openings also created escape paths for tugs caught on the wrong side of a wake.

Halvek enlarged the floor image on his display. "Three gaps permit the adult to drift back toward Brine's plane."

Irian joined from Accord of Dust. Her bridge showed thirty-seven distributed sighting nodes across the convoy. "Then my mass moves the other way."

"You cannot turn seventy million tonnes on command," Halvek said.

"I can schedule existing thrust so our center of mass does not deepen the Brine-side gradient."

"That separates your heavy modules from their tug screens."

"It separates them by twenty kilometres, not by a route."

Kessa put a second coil of power line beside the first. "Irian staggers mass. Continuity shapes the outer slope. Local cage beams open the juvenile wakes. Cutters and routekeeper tugs keep sighting between all three."

Sena picked up one of the black fasteners. "And Threadbare?"

Kessa placed it where the cable crossings grew densest.

"Of course," Sena said. "The least armored ship goes where every bad solution meets."

"We carry the cold-shear tool."

"We also carry a pilot with objections."

"Log them."

"I have. The file affects our trim."

Dry laughter moved through the planning channel, brief enough not to hide the strain.

Anu left the workbench and knelt by the model. She removed Kessa's washer for Continuity and placed it farther from the adult. "Your gradient reaches through the juvenile chain here. The adult may follow. A wounded juvenile cannot tolerate the same slope."

"We used six parts in ten million at Sable."

"For one injured animal across one trough. The others have different cage scars."

"How much?"

"Start at four. Rise only if their pulse delays shorten."

Halvek objected. "At four parts, Continuity cannot shift the adult before its current track crosses the empty edge of Brine's freight plane."

"Empty today," Anu said. "Do not injure it to protect an orbit we already cleared."

"That plane intersects the convoy approach six hours later."

Irian answered before Kessa could. "Then the approach moves. My people voted for published losses, not for a fixed schedule."

The cable model widened until people had to step around it. Kessa marked thermal limits beside each washer. Continuity could sustain a diffuse field for seven minutes at current radiator damage. Neutral cutters could cast narrow ranging beams but lacked strength to shape the adult. Routekeeper tugs carried salvaged resonator heads from opened cages. Their projectors varied in age, output, and legal maintenance history. Two had been designed to inspect freight collars rather than hold space.

That inconsistency helped. A single hidden command could not seize the whole formation.

Kessa divided control into four permissions. Routekeepers owned juvenile release. Anu owned biological stop limits. Irian owned convoy mass timing. Rusk owned ship safety and collision avoidance. Kessa would coordinate the moving gradient but could not override any stop.

Halvek watched her write the permissions onto the deck. "You have created four ways to abort."

"Yes."

"And no single way to continue."

"Also yes."

He looked almost offended by the elegance of it.

They moved to a live test using an empty freight shell released near the adult's outer wake. The shell carried six clocks, two calibration masses, and a transmitter nobody trusted. Routekeeper Tug Mended Question projected the first open slope. Neutral Cutter Civic Grace ranged from the opposite side. Continuity remained dark.

Sena flew Threadbare along the test boundary. Kessa felt the tug's structure through her boots while the shell crossed the artificial gradient. The forward grapple drum gained load. A panel in the centrifugal passage began to chatter at

eleven hertz.

"Local slope five point one," Pell reported.

Anu shook her head. "Commanded four."

"Cage head has an old focusing bias," Orra Senn said from Mended Question. "We calibrated it against Charter references."

"Those references assumed a fixed hollow," Kessa replied.

Senn dropped the beam. The shell drifted clear.

Kessa opened the projector's raw output on her slate. The bias came from a correction table installed twenty-three years earlier. It increased power whenever target geometry moved away from center. Useful for preserving a corridor. Dangerous for offering a slope that needed to remain open.

"Strip motion correction from every released cage beam," she said.

A routekeeper captain at Nacre answered, "That leaves pointing lag across the whole array."

"Then humans lead the target."

"By how much?"

"Sena?"

The pilot inspected the adult's current curvature. "Depends which image you want to crash into."

Kessa waited.

"Local rates," Sena said. "Each tug leads from two pulse samples. Nobody imports lead time from another node."

The routekeepers rewrote their tables. Seventeen projectors across the chain went dark for manual conversion. During those minutes, the adult advanced without human guidance and harmed nothing. Kessa kept noticing that fact.

The second test began at four parts in ten million.

Mended Question cast an open slope ahead of the freight shell. This time the local clocks measured four point two. Civic Grace tracked the shell's far side. Two routekeeper tugs passed raw ranges to each other without routing through Threadbare.

"Add Continuity," Kessa said.

Rusk authorized Projectors Two and Four at minimum diffusion. The cruiser's field joined the tug's slope from forty thousand kilometres away. Where both gradients overlapped, their combined curve steepened beyond Anu's limit.

"Cut Four," Anu said.

Rusk cut it before Kessa repeated the order.

Projector Two remained. Its field pushed the calibration masses along the intended path while leaving an open region behind them. The freight shell turned

six degrees and settled into the adult's outer wake.

Halvek highlighted the overlap. "Military formation would offset projectors by range and fire time. Your nodes are treating simultaneous arrival as the goal."

"Can you produce an open slope with staggered arrival?" Kessa asked.

"Yes."

"Without central fire control?"

He paused. "With a shared timing table and local release authority."

"Build it."

Halvek moved to a side console under Rusk's observation. His geometry divided Continuity's nine beams into three traveling sets. Each set opened ahead of the adult and decayed behind it. No beam crossed another at full strength. Routekeeper projectors filled the gaps at lower power. Neutral cutters marked the edges and held no shaping authority.

The pattern came from convoy defense: guide an incoming mass away from vulnerable ships without concentrating fire into a debris cloud. Halvek stripped every weapon assumption and left only timing.

Kessa disliked how useful it looked.

Anu examined the decay. "Your second set closes for point eight seconds."

"Within instrument uncertainty."

"Not within tissue."

Halvek widened the release interval. The closed contour disappeared. Brine-side leverage weakened.

Irian adjusted convoy thrust by three minutes. Her staggered mass moved the natural gradient enough to recover half the lost effect.

They ran the model again.

Adult path shifted outward. Juvenile wake alignment improved at seven of eight remaining cages. The wounded Sable juvenile remained matched. One Nacre hollow showed a predicted contraction above Anu's limit during core release.

Kessa moved two tugs from Brine to Nacre. That left a sighting gap beside the convoy.

Irian assigned an empty cargo shell as a stationary node. "It has clocks and laser."

"It has no pilot," Sena said.

"It does not need to decide. Neighboring crews do."

Kessa added the shell. The formation held in simulation for one full pulse cycle.

Before accepting it, Kessa forced a communication fold through the model. Every long-range channel received a different delay drawn from the adult's measured lensing. Continuity saw Nacre's release fourteen seconds late. Brine

received Irian's mass table before Accord transmitted it according to the bridge display. One neutral cutter vanished behind a false image of its own drive plume.

Central coordination collapsed immediately. The local pairs did not. Mended Question kept its beam dark when its neighboring tug failed to confirm the trough. Nacre delayed middle-station release rather than trusting Continuity's stale permission. Two convoy clusters continued on their published thrust because neither had received a verified change.

Halvek marked the lost efficiency. "The adult shifts only half the required distance under this response."

"It also receives no accidental hold," Anu said.

Kessa moved a routekeeper tug into the missing cutter's place. "We do not solve delay by guessing through it. Each node continues its last safe condition. Dark for projectors. Published thrust for convoy mass. Local drift for sighting ships."

Irian added, "Any cluster that loses both neighbors exits through its nearest open gap. It does not chase the crossing line."

Sena traced the escape vectors on the cable floor. One passed close to Threadbare. She shifted their nut aside. "Nearest open gap now has room for two frightened ships and one chief who thinks in straight lines."

Kessa accepted the correction. The communication-fold run completed with a weaker path and every contour open. No model awarded points for elegance.

"Run failures," she said.

Rusk disabled one neutral cutter. Sightings rerouted through two tugs. Orra Senn killed a cage beam during outer release. The gradient weakened but remained open. Irian removed Accord's timing feed. Distributed nodes preserved local thrust order for ninety seconds, enough to carry the convoy until a new mass table propagated.

Anu failed every filament sample at once.

The proper response required all shaping beams to cut. Continuity did. Six routekeeper heads did. One old projector at Brine continued because its local operator had configured biological stop as advisory.

Kessa's voice sharpened. "Who owns Brine Head Five?"

A rigger named Dalen Vos answered from the damp station. "I do."

"You do not own the stop."

"Local rules require supervisor confirmation for a full power cut."

"The union refused those rules on Day Twenty-six."

"Refused new holds. This beam guides."

"Guidance without an enforceable stop becomes a hold the moment the animal crosses the wrong line."

Vos went quiet. Condensation drifted past his camera. Behind him, old cage controls showed the Charter seal under layers of scratched annotations.

"Then who carries liability if we cut at the wrong moment?" he asked.

"I do," Kessa said.

Marl's voice entered from Accord. "No. That repeats the same problem with a more popular chief."

Kessa closed her mouth.

Anu tapped the permissions slate. "Biological stop comes from measured contraction. Any two local nodes may call it. No supervisor may delay. Liability follows the published rule, not one person."

Vos read the amendment. "Give me a physical cutoff."

Orra Senn designed one from a grapple squib. Every released cage beam would carry a hard line to two neighboring tugs. Either could open the circuit. The system added mechanical veto to the four-part authority.

During the next failure run, Brine Head Five cut within three tenths of a second.

Vos grinned through the damp. "Now it listens."

"Machines do that better when the wiring agrees," Kessa said.

A young rigger beside him leaned into frame. "Looks like a shepherd's net from here."

The channel went briefly still.

Kessa looked down at the cable spread across Threadbare's floor. The phrase carried an old human confidence: animals directed for human purpose, boundaries thrown around moving bodies, care and ownership braided too tightly to separate. She did not want a name that made domination sound gentle.

"It does not catch anything," she said.

The young rigger shrugged. "A good net leaves the way open behind the flock."

Anu's expression sharpened at flock, but Sena spoke first. "Crews need a channel name shorter than 'distributed open-gradient formation with biological veto.'"

"Call it Formation Forty."

"Already used for a waste convoy."

Halvek said, "Names affect discipline. If the name suggests enclosure, crews may tighten the geometry under stress."

Kessa had not expected help from him on that side of the argument.

Marl answered, "Then define the name before somebody else does. Net of sightings, not a fence. Shepherding ships away from collision as much as animals away from orbital planes."

Kessa watched the adult's broad lens move across the plot. Humanity had

pinned its juveniles for one hundred sixty-eight years and called the wounds roads. One improvised formation could not turn that history into stewardship. It could only perform the next piece of work without repeating the injury.

“Channel designation Shepherd Net,” she said reluctantly. “Open gradients only. No closed contour. Any two nodes cut it. Put that definition in every header.”

The name propagated across ships, tugs, and routekeeper stations. The Shepherd Net appeared on the plot not as a mesh but as changing relationships: sighting lines, beam windows, escape gaps, and local veto pairs.

Preparation moved from model to hardware.

Continuity rolled to expose its repaired radiator bank. Routekeeper crews locked independent clocks onto all nine resonator trunks. The three neutral cutters spread beyond the adult’s projected leading curve. Their weapons remained sealed. Tugs from Nacre, Brine, and Orison carried released cage beams into positions no route manual recognized.

Irian began convoy thrust in staggered clusters. The movement looked almost too small to matter. Across 70.4 million tonnes, minutes of timing shifted the mass center away from Brine’s orbital plane and opened working room near the adult wake.

Threadbare crossed from node to node with the cold-shear cutter secured beneath its forward rail. Kessa checked every physical cutoff. Sena verified local lead times. Pell found one clock sharing power with a heater and moved it to an isolated cell. Anu rejected two gradient settings after fresh filament samples showed contraction.

Halvek transmitted his final timing table. “Traveling Set One opens on the adult’s first beat. Set Two follows after local trough confirmation. Set Three remains dark until the wounded juvenile clears.”

“No automatic progression,” Kessa said.

“Each set requires local routekeeper release.”

“Good.”

His image remained on the corner of her slate. “Rho, Continuity can stabilize the outer node if something fails.”

“At what cost?”

“The cruiser enters the gradient deeper than planned.”

“That is not today’s solution.”

“No. It belongs in the failure table.”

She added it without pretending the possibility carried no human crew.

By the time Threadbare reached its central sighting position, the Lumen Reach had rearranged itself around moving life. Fixed corridor marks remained dark. Released juveniles traced narrow wakes toward the adult. The convoy waited in

staggered clusters. Twelve thousand people watched from provisioned shelters beyond the crossing line.

Kessa clipped Tomis's torque key beside the local load pickup. Its obsolete cavity registered physical stress without accepting Charter classifications. She placed her left palm over the grapple console. The scar there had faded to a pale interruption, less reliable than the tools and impossible to ignore.

"Every node report," she said.

One by one, the formation answered.

Continuity: nine projectors manual, routekeeper certified.

Neutral cutters: three sighting arcs clear.

Nacre beams: outer stations open, middle stations ready.

Brine routekeeper tugs: hard cutoffs live.

Irian: convoy mass on schedule, distributed nodes active.

Anu: filament contraction below limit, biological stop armed.

Sena: Threadbare aligned inside the central ranging gap, all exits ugly but available.

No answer promised success. Each reported a condition somebody could verify.

Ahead, bent starlight climbed over the adult's unseen back. The remaining juveniles answered from their cages with uneven loads. Kessa felt the first beat enter the tug through Tomis's key, the second through the grapple drums, and the third through every cable laid against the hull.

Across the Shepherd Net, ships took their positions.

The final migration pulse began.

Chapter 25 — The Crossing of No Roads

Kessa watched the first ship leave the last line on every chart.

It went sideways by instruments and forward to the eye, a Brine water tender carrying three hundred people and enough seed culture to restart six vats. Released hollows had drawn a shear thread through the dark ahead of it. The thread showed only as a kink in three stars and a disagreement between clocks. No corridor mouth opened. No resonator held a throat stable. The tender entered on a burn calculated by forty-one ships and immediately vanished from Threadbare's trustworthy geometry.

"Node Four still sees her," Sena said.

Kessa kept one glove on the tug's manual brass rail. Tiny load changes traveled through the hull as the Shepherd Net shifted around the adult veilback. "Ask Four for raw angles. No composite."

Pell relayed the request. A moment later, a child's drawing slate tied into the sighting bus displayed three chalk-colored lines. One came from a routekeeper tug. One came from a seed barge with an old survey cupola. The third belonged to a habitat observatory that had never expected to steer anything larger than its own mirror.

Their intersection placed the tender nine kilometres from the fleet solution.

Sena corrected the receiving mark. "Nine becomes ninety if everyone trusts the average."

"Then nobody trusts it." Kessa opened the fleet work channel. "All ships, reject composite position for Tender Brine Two. Carry Node Four's raw triangle. Do not chase her apparent drift."

The order repeated outward through human voices because the network could no longer guarantee sequence. Irian had issued the manual slates on Day Eleven, when Tern broke the convoy into pieces and automatic route solutions began lying in different directions. Now those battered boards carried ship names, clock offsets, sighting pairs, and correction limits in grease pencil. Some had been made for schoolrooms.

Tender Brine Two reappeared twenty-two seconds later, exactly where Node Four had placed her. Her fusion plume bent into a pale hook. Then the ship crossed the shear thread and emerged beyond the final anchor plane.

A cheer started on a civilian channel.

Irian cut across it. "Save breath. We have seventy million tonnes behind her."

The second vessel entered too high. A family carrier named Copper Mercy had retained one automatic correction layer after its captain misunderstood the order. When Node Two's mark shifted, the layer fired both port tugs against a position

already six seconds old. The carrier began to yaw with four hundred occupied berths along its spin band.

"Kill correction," three voices said at once.

Its captain killed the wrong bus. Cabin lights vanished across one third of the hull, but the tow program continued pulling. On Kessa's slate, local marks opened like snapped jaws.

Sena selected a direct channel. "Copper Mercy, your port tug owns the stale solution. Cut its data, not its power."

"Port says star pair stable."

"Stable on yesterday's road," Kessa said. "Ask your aft blister what it sees."

A teenager answered from the blister observatory. His voice cracked while he read angles from a manual reticle. Node Six confirmed his pair. The captain isolated the port feed and handed thrust to the blister crew. Their first correction came late, the second came rough, and the third brought the carrier through with enough clearance to spare its antenna forest.

Emergency lights returned after the ship reached ordinary geometry. The teenager kept reading marks until another navigator relieved him. He had occupied a node and carried four hundred berths where no central system could.

Accord of Dust lay six hundred kilometres aft, eleven kilometres of truss and turning habitats amid barges, tugs, cylinders, tanks, and shelters. The convoy moved like machinery dismantled in motion, held together by fuel margins and people reading separate stars.

Behind all of them, the adult bent half the visible field around its vast moving topology. Eight juveniles pulled at the last cages in answer to its pulse. Three already moved free, while Sable's wounded animal lagged outside their curve. The Shepherd Net held no creature. Its cutter beams and tug masses shaped gradients along open sides, trying to keep the molt corridor clear of Brine's inhabited plane.

Three beats entered Threadbare through the deck.

Kessa checked the pulse clock. "Next trough in seven minutes. Bring the hospital cylinder through before it closes."

Kindly Argument had lost two navigation arrays at Tern. Its hull still carried a white scar where an exclusion cone had taken Charter fire at Orison Gap. Four sighting nodes bracketed it now. Each sent unmerged angles to the hospital's bridge, while routekeepers spoke the corrections aloud.

The cylinder crossed without incident. A grain barge followed. Then came two Brine habitats, a machine-seed carrier, six fuel bladders on a common tow, and the forward drum of Accord with its rotation slowed to protect the bearings. Every passage altered the thread. There could be no fixed timetable because every mass changed the next ship's road.

At the fleet pit, Irian refused three requests to move guidance back onto Accord.

Kessa heard the last refusal over the shared channel. "My carrier cannot see around its own freight," Irian said. "Keep authority at the nodes that hold the angles."

A Charter cutter captain answered, "Central helm could resolve conflicting commands."

"Central helm could issue one mistake to everyone. Maintain distributed sighting."

The cutter dropped the argument. Its pilot began reading Node Seven's marks instead.

Sena touched two fingers to her display. "Habitat Wren has a tow mismatch."

Wren showed as an empty habitat module near the convoy's middle. Twelve thousand people had chosen shelters in the Reach rather than the crossing, and Irian had provisioned them before the fleet turned. Their evacuated modules still carried machinery that could not be replaced: air roots, water recovery organs, soil drums, foundries, nursery walls, and power buses old enough to have become architecture. Wren had served families for seventy years. Its spin shell now carried no one, but two cargo crews rode the tug pair moving it.

Kessa pulled the raw marks. Wren's two tugs agreed about thrust and disagreed about position. A shear fold had slipped between them. The forward tug saw the module eight metres high. The aft tug placed it twenty-one metres low.

"Both can be right," Sena said.

"They won't stay attached if they are."

Kessa switched channels. "Wren tow, drop common autopilot. Each tug hold local load only. Report cable phase."

Forward tow answered first. "Red cable cycling at four seconds."

Aft tow said, "Blue at six. We have rotation coming into the spine."

Wren's long cylinder rolled by a fraction. Starlight along its hull split into two images, then four. One tug pulled against a position the other had not reached. The common tow frame took the difference.

"Evacuate both crews," Irian said.

The forward pilot protested. "We can dump the machine deck and save the shell."

Kessa examined the load path. Wren's mass could cross if the two tugs entered the same local geometry within less than half a second. Their clocks differed by three seconds under the fold. No signal could tell either pilot which second belonged to the other.

"Not with people aboard the tugs," she said. "They'll have to leave controls live and come off by service pods."

Wren carried no residents, yet twelve technicians worked its tow. The fleet had

treated empty as permission to risk it. Kessa felt that old habit in the speed of their planning. Machinery without bodies became expendable only after someone forgot who would need it later.

Irian did not forget. "What can be removed in twelve minutes?"

"Seed cores, memory rods, two water cultures," the module keeper said. Her voice remained level until she named the nursery archive. "And seven decades of birth records if the rack releases."

"You have nine," Kessa told her. "The next fold cuts your pod lane."

Work channels multiplied. Cargo crews entered Wren through opposite hubs while the tugs maintained local load. Kessa assigned Threadbare to the forward node, close enough to throw grapples if a pod drifted but not close enough to add uncontrolled mass.

The module keeper went back for the archive herself. Her name, Irian's roster showed, was Dava Pellin. She had lived in Wren for fifty-eight of its seventy years and knew which deck plates lifted without tools. A helmet camera followed her through an unpowered nursery where painted animals walked around the curved walls. The pictures had survived six changes of settlement ownership. Pencil marks beside one door recorded children growing upward until spin made the direction seem obvious.

"Archive rack jammed at the lower rail," Dava said. Her breath sounded too loud in the channel.

Kessa watched the tow loads. "Leave the casing. Pull the memory rods by hand."

"The rods lose indexing outside the rack."

Anu answered from a biological survey node. "Wrap each bundle with the label strip. I can rebuild the index from order and checksums."

Dava removed her outer glove to reach the recessed latch. Kessa nearly ordered her to stop, then saw the keeper had isolated the compartment and tied the glove to her wrist. Old hands worked the latch by touch. The first rail released. The second remained bent under spin load.

"Wren, forward tug phase just shortened," Pell warned.

Seven minutes remained before the pod lane folded. Dava braced one boot against the nursery door and hauled. The rack came free hard enough to drive her shoulder into a painted antler. Loose growth records fluttered past her camera, paper kept because children liked finding their own names without opening a screen.

She gathered none of the pages. She secured the rack and pushed toward the hub.

"Keeper, you left documents," a cargo tech said.

"I left copies," Dava replied. "I brought the births."

The tug crossed one minor fold under Sena's hands. Stars leaned, recovered, then leaned the wrong direction. Kessa read the hull through her boots. A route had once protected ships from this kind of argument. It had also turned a living body into a fixture so no pilot needed to feel the dispute.

"Forward node just went blind," Pell said.

Its signal vanished from the slate. Not noise or power loss. The node's carrier still answered status calls, but every sighting arrived with one star duplicated into six incompatible positions.

Kessa found the ship on external view: a routekeeper launch called Skein, running beside Wren with a survey mast built from cage inspection gear. One mast hinge had opened under differential pull. The array pointed through its own exhaust haze.

"If Skein stays blind, Wren's pods lose their near mark," Sena said.

"Put us alongside."

"Geometry won't hold for docking."

"Then don't dock."

Threadbare moved across the launch's apparent path. Sena trusted load, plume, and two distant observations rather than the glittering lie in the cupola. Kessa sealed her helmet and entered the forward lock with Vasken. The rigger carried a spool clamp, a line gun, and no suggestion that someone else should go.

Outside, the Shepherd Net filled space with separated points of light. Continuity held the strongest position aft, its nine beam ports tracing faint red lines past the adult. Neutral cutters moved as shepherd masses along the open edge. Routekeeper tugs occupied the dangerous inner nodes. Far beyond them, the leading convoy appeared as scattered sparks with no corridor walls to make them one thing.

Kessa clipped to Threadbare's rail. "Match Skein's mast root, not her hull."

Sena rolled the tug. The launch seemed to tumble beneath them, although Kessa's suit load stayed steady. She fired the line gun. Its hook curved away, came back from a direction no straight cable should permit, and caught the broken mast below the hinge.

Vasken locked the spool clamp. "Line says nine tonnes."

"My arm says five."

"Split the difference?"

"Not unless you brought half an arm."

They paid out line until the suit load and tug drum agreed. Kessa pulled herself toward the mast. The gap crossed twenty metres by laser and perhaps fourteen by cable. She kept her eyes on the braid. Space could offer as many images as it liked; tension still had to arrive somewhere.

At the hinge, a locking tooth had cracked. One half remained seated while the other floated three centimetres away, held apart by local gradient. Kessa could not force the pieces together without twisting Skein's hull.

"Cold cutter," she said.

Vasken passed it along the line. "You're cutting off their array?"

"I'm cutting off its bad idea."

She severed the cracked tooth, rotated the mast on its surviving pin, and drove the spool clamp through two maintenance eyes. The repair would never pass inspection. It only had to hold an angle long enough for twelve people to leave Wren.

A service pod emerged from the habitat's forward hub.

Its pilot called, "No near mark."

Kessa slapped the mast housing. "Give them one, Skein."

The node sent a raw star pair. The pod's course changed by three degrees, carrying six technicians and two seed cases toward a receiving barge. A second pod followed with the remaining crew. It trailed a cargo net full of dark cylinders.

"Birth rack?" Irian asked.

The module keeper answered from the pod. "Released whole."

Wren rolled again. One tow cable went slack. The other climbed toward failure load.

"Cut both tugs free," Kessa said.

The aft pilot hesitated. "If we release, it crosses the fleet track."

Sena had already laid the projection. Wren would drift behind the next convoy cluster if freed now. If a tug held five seconds longer, the module could strike the machine-seed carrier sideways.

Irian spoke on the command circuit. "Tow crews, release Habitat Wren."

No one moved for one second.

"Release," the module keeper said.

Both cutters fired. Blue and red tow lines recoiled into darkness. Wren continued under its inherited rotation, window bands unlit, soil drums secured behind layers of metal. Seventy years of pumps, repairs, meals, arguments, and measured childhood heights crossed the sighting slate as a mass with no valid destination.

A cargo pilot asked whether a spare tug should follow.

Irian answered, "Negative. Mark it and clear the next passage."

Kessa returned along the line while Skein's repaired mast tracked the empty habitat. Wren drifted toward the wake's unstable edge. Its hull lengthened in bent light, narrowing until the cylinder looked like a bright wire. Then the shear took the spin shell. One end moved ahead of the other by a distance no structure could

absorb.

The module folded without flame.

Its pressureless decks opened in a line of pale fragments. Soil and machine housings spread along the fold, each piece following a separate curve. The nursery archive had made it off. The water cultures had made it off. The building itself did not.

No cheer followed the rescue.

Vasken pulled Kessa onto Threadbare's rail. "Mast holds."

"Leave the clamp."

"That was our good one."

"Now it's their bad one."

He laughed once, without pleasure, and entered the lock.

The convoy resumed. Wren's loss reduced the mass problem but worsened every future settlement calculation. Irian's logistics crews redistributed air-root capacity before the fragments had vanished. Marl Quade placed the rescued technicians among three ships rather than letting a single captain claim their expertise. No ceremony delayed the crossing.

By the next pulse trough, Accord of Dust reached the thread.

The carrier could not enter as one rigid body. Tug clusters pulled its attached habitats into a controlled curve while sighting nodes called local positions. Irian's voice stayed off the guidance net unless a conflict required command. Kessa heard other people carry the ship: a Brine observatory keeper, a Charter pilot from a neutral cutter, a school navigator reading grease marks, Sena correcting a clock offset from Threadbare's scarred cupola.

"Forward truss across," someone said.

"Habitat band three sees clean stars."

"Fuel farm low by twelve metres local."

"Do not correct. Twelve belongs to Node Nine's clock."

Halfway through, two nodes exchanged names. A neutral cutter had inherited the call sign of a routekeeper tug during the Orison rescue, and both still answered to Seven under pressure. One sighted Accord's seed vault. The other watched a train of water bladders two hundred kilometres away. Their angles entered the spoken net under one label.

The carrier's starboard tug cluster began a correction toward the wrong mass.

Irian could have frozen every helm from her logistics pit. Kessa saw the command request appear and remain unanswered. Instead Irian called Marl.

"Delegate check. Which Seven has local trust?"

Passenger stations polled their assigned ships. Replies came by voice, slate

flash, maintenance carrier, and one line-of-sight lamp from a vessel with no working transmitter. Marl returned two new labels: Seven-Cutter and Seven-Tug. The mistaken angles separated before Accord accumulated enough sideways motion to endanger its bearings.

“Record both designators across every slate,” Irian said. “No automatic rename.”

Her bridge could have corrected the confusion faster for one minute. Leaving the correction distributed made it harder for the same error to capture everyone at once. Kessa heard the discipline in Irian's silence after the order. A commander trained to gather control had refused it while her own ship bent across the dark.

The mass carrier bent to the eye. Its central truss curved around nothing visible. Kessa knew metal could not tolerate that shape. The apparent bend belonged to light and separated local frames, but knowledge did not soften the sight.

Three beats passed through the tug again.

This time the adult answered close enough to move every unfastened tool in Threadbare's repair gallery. The hull creaked from bow to drum. Behind the convoy, darkness lifted across forty thousand kilometres. Lines of bent stars peeled away from the adult's back as if an immense skin had loosened.

Anu entered the work channel. “Topology change along the dorsal lens. Not a pursuit response. The molt has started.”

Kessa looked aft. Eleven juvenile signatures tightened along the chain toward the adult's wake. The wounded Sable animal lagged outside the common curve. Around them, the Shepherd Net adjusted node by node.

Ahead lay no charted anchor, no green cage status, and no authority capable of flattening the measurements into one approved line. The convoy's leading ships burned in ordinary dark, beyond every fixed route humanity had built.

Sena eased Threadbare across the final shear boundary.

The last anchor stars straightened behind them. Then the adult opened another luminous fracture through the dark, and its old shape began to come apart.

Chapter 26 — The Molt

The adult opened along a line no instrument agreed existed.

Bent stars tore apart behind the convoy. For half a second Kessa saw the Shepherd Net repeated in six false skies, every tug and cutter occupying several incompatible positions. Then Threadbare's displays rejected the images, leaving only raw loads, clock offsets, and the three-beat pulse moving through the hull.

Sena held the tug against a gradient that changed faster than the engines could answer. "I have two sterns."

"Fly the one pulling on us."

"I preferred the other."

The cupola darkened as the adult's topology unfolded across forty thousand kilometres. Its baryonic core remained unseen, small against the lens body around it. What opened had no fleshly edge. Starlight stretched across translucent fractures, and each fracture carried the wake of a creature changing from migratory body to something larger and less compact.

Eleven juvenile signatures tightened along the migration chain. Three had traveled free since the nine-minute dark. Eight remained inside cages whose outer stations had begun going dark as the Shepherd Net formed. Each compact topology waited at a different point along the pulse cycle.

Sable's wounded juvenile remained outside the curve.

Anu sent a biological limit map to every net node. "Do not force alignment. We can shape the gradient ahead of it. We cannot pull it into phase."

One Charter pilot asked, "What happens if it misses the molt?"

"We have one dead adult showing that answer," Anu said. "Keep your beam off the animal."

Kessa expanded the release board across her console. Twelve circles marked the migration chain. Eleven carried live timing. Sable blinked between signals as scarred filaments failed and regrew. The safe sequence discovered in the dead route still governed every transition: outer three, contraction wait, middle three, core triad during the pulse trough. No central command held these juveniles now, but their own folded geometry followed the same order as they left the cages and joined the adult.

"First group approaching trough," Pell said.

Kessa touched the fleet channel. "Nacre, Brine, Morrow Span, confirm outer release."

Three routekeepers answered with load values, not confidence. Nacre's juvenile loosened first. Brine followed. Morrow Span, carrying old cage scars, held one outer fold longer than predicted.

“Do not advance Morrow Span,” Kessa said.

A cutter beam brightened at its flank, shaping an open gradient toward the adult. Morrow Span's fold released. All three signatures moved inward.

The next pulse reached them.

Three beats. The first loaded every grapple drum on Threadbare. The second made Kessa's old palm scar prickle inside her glove. The third crossed the net and returned through eleven hulls at different intervals.

“Middle release now.”

Routekeeper tugs rolled, putting their masses across unwanted slopes. Neutral cutters reduced beam output in sequence. The juveniles unfolded without the violent snap Kessa remembered from Tern. Their wakes joined the adult's fractures, thin curves merging into a broader moving surface.

For one minute the plan worked exactly as drawn.

The Orison group entered next. Their three juveniles had lived inside linked cages whose control software treated them as one corridor machine. Release crews had severed that logic, but the animals still carried mismatched hold scars. One opened its middle folds early. Another remained compact through a full trough. The third drifted toward the first as their wakes crossed.

“Separate them with mass, not beam,” Anu said.

Two former Charter cutters moved between the signatures with drives off. Their armored hulls offered a shallow gradient each juvenile could pass around. Kessa called the release from local clocks while routekeepers at Orison read filament contraction through abandoned cage sensors. Nothing synchronized cleanly. One cutter rolled six degrees under the load and lost an antenna panel. The juveniles curved apart, completed their middle release, and took separate places along the adult's open flank.

The antenna panel did not drift clear. Orison's middle juvenile caught it in a shallow lens pocket, where the sheet of armor began circling a filament branch. Every pass drew it closer. No animal chose the metal. The local gradient treated it as available mass.

“Panel impact in forty seconds,” Pell said.

A routekeeper tug named Second Wrench held nearest, but its projector shaped the open path for the third juvenile. If it moved, two damaged wakes might cross again.

Kessa searched the Net for another mass. The lost panel measured twelve tonnes. A direct beam could push it, but the beam would close across living tissue for nearly a second.

“Cargo shell Eighteen,” Irian said over the shared board. “Empty, no crew, two working thrusters.”

The shell waited outside Orison's local fold as a distributed sighting node.

Moving it would blind one angle on Accord's trailing water train.

"Can your convoy carry the gap?" Kessa asked.

"Nodes Eleven and Fourteen can cross-sight for ninety seconds. After that the water train reaches the shear."

"Ninety is enough."

Local crews took the shell. Its command receiver saw the panel in the wrong position, so a pilot on Second Wrench spoke each thruster pulse while Irian's sighting nodes called raw angle. The empty shell entered the lens pocket broadside. For several seconds it seemed to move away. Tension on its service loop showed approach.

"Impact," Pell said.

The two masses met at walking speed. Cargo Shell Eighteen took the panel across its empty hold and began to spin. Its thrusters fired once more, carrying both pieces out through an open edge. Node Fourteen inherited the sighting load before the water train reached the gap.

The middle juvenile completed its release without metal crossing its filaments. The shell and panel drifted toward an unoccupied recovery orbit nobody would visit until the molt ended.

Kessa marked the node dark and heard Irian acknowledge the lost equipment. Neither treated a disposable hull as costless. The shell had bought a living clearance and left the convoy with one fewer pair of eyes.

Two distant teams followed. Their pictures arrived too late to guide Kessa, so command belonged to people beside each former cage. She heard confirmations after the actions had happened: an outer trio dark at Pale Reach, contraction holding beyond Orison, core release complete beside a station whose name she had seen only on license forms. The Net carried consequences rather than orders across those delays. The three juveniles already free began their own compact release along the adult's wake, including Tern with its uneven scars.

By the time eleven signatures aligned, hundreds of workers had made decisions no central helm could revise. Kessa's board showed a coherent migration curve built from local acts, each one small enough to fail without permission.

Then Brine's orbital alarms filled the channel.

A new lens edge had appeared above the inhabited plane. It ran toward the agricultural cylinders and the convoy's trailing stores. No creature changed direction. The adult's unfolding topology simply occupied more space than their measurements had allowed.

Irian spoke from beyond the shear boundary. "Time to plane crossing?"

"Sixteen minutes at current growth," Sena said.

Anu corrected her. "Nine if the ventral folds open next."

The Shepherd Net shifted. Four routekeeper tugs burned toward the inner edge. Two neutral cutters moved their beams outward. Continuity held the aft node, its nine resonator ports projecting the strongest movable gradient any human ship carried.

Kessa dragged the net geometry by hand. "Node Three must move forty kilometres spinward."

"Node Three is a fuel barge," Pell said.

"Then it needs help."

Irian assigned six tugs without taking their controls. The barge began its slow relocation, but the lens edge outran it. Local clocks separated. Guidance calls arrived out of order. A tug acknowledged an instruction Kessa had not yet sent.

The adult opened another fold.

Every work light near Brine bent toward the cylinders. Transfer spines flexed under tidal load. A vat habitat reported bearing alarms. The convoy's distributed sighting nodes tracked the danger from outside, but observation could not provide mass where the net had left a hole.

Halvek entered Kessa's direct channel. His face did not appear. Only his voice and Continuity's raw beam table came through. "The cruiser can occupy Three."

"You cannot reach it before the ventral opening."

"I can if we stop pretending the ship needs to leave."

Kessa studied his proposed burn. Continuity would cross two shear folds, discharge most maneuvering reserve, and settle broadside inside the failing node. Its hull mass could stabilize the local gradient. The nine resonator beams would spread the load until the juveniles completed release.

Afterward, the cruiser would have no path out.

"Your bridge is under restriction," Kessa said.

"My officers can verify the burn."

"That does not answer me."

"It answers the geometry."

A second voice joined, Captain Orra Senn from Mica Hand. She coordinated the cutter locked to Continuity after its crew accepted neutral rescue status. "Enro remains under restricted watch. I have two officers aboard his bridge and a cutter locked to his ventral port."

"Crew count?" Kessa asked.

"Four hundred twelve remain on Continuity."

The cruiser had already evacuated specialists and nonessential watches before entering the Net. Four hundred twelve still exceeded any acceptable sacrifice.

Halvek said, "We can clear all but the placement crews in seven minutes."

"You have less than nine."

"I know what less means."

Kessa heard his old arithmetic and hated that it fit. "Begin evacuation. No one stays because you call the ship necessary."

"Agreed."

Senn did not soften. "Marshal, you leave on my cutter. Your arrest does not end with your command."

A pause held long enough for Continuity's evacuation alarm to enter the channel. "Understood," Halvek said.

The cruiser broke position.

Its departure opened the aft edge of the Net, but three routekeeper tugs moved into the temporary gap. Continuity burned across their sterns with beam ports dark and cutters clustered around its hull. Escape pods and service launches streamed from both docking bays. Every departing craft altered the burn. Halvek's bridge crew compensated by changing beam mass rather than demanding a clear lane.

Kessa watched names move from cruiser roster to receiving ships. Navigation. Reactor maintenance. Medical. Galley. Beam control. Damage crews. No category carried the word expendable.

At three hundred eighty-six remaining, the roster stopped changing.

"Dorsal bay reports full," Pell said.

The receiving cutters had berth volume for more bodies but not for more launch mass. Two service boats waited inside Continuity with loaded crews and insufficient propellant to cross the moving fold. The cruiser could keep them aboard for the placement burn or strip fuel from its maneuver reserve.

Halvek opened the tank table. "Transfer port attitude reserve to both boats."

Rusk objected from the bridge watch. "You need that reserve to hold broadside in Node Three."

"Then we transfer starboard."

"Starboard feeds your final roll."

Every tank supported a later action. Kessa recognized the trap from salvage jobs where damaged machinery made all remaining functions look essential. Human bodies could not remain the adjustable margin.

"Empty two beam coolant tanks," she said.

A beam officer answered, "Without coolant, Projectors Six and Eight lose seven seconds of service."

"How many seconds does the Net require?"

"Unknown until the ventral fold opens."

Anu placed the biological limit over their table. Seven seconds might separate

an open gradient from injury. Keeping the boats aboard might place eighty-three crew inside a hull already committed to loss.

Irian entered with a third option. "My outer fuel train can send a bladder, but it reaches you after first fold contact."

"Too late," Halvek said.

Kessa examined the service boats. Their tanks lacked enough propellant for a free crossing because evacuation planners had budgeted them as dock-to-dock craft. They did carry pressure and docking thrust. A neutral cutter could tow both if someone built a common line before Continuity reached the fold.

"Ventral cutter takes them in train," she said. "Boats burn only to clear the bay. Cutter supplies translation."

Senn calculated the tow load. "My stern eyes carry one boat by code."

"Code assumed weapons and full armor."

"We still have armor."

"Lose the empty missile rack."

Senn's crew blew eight rack panels and their mounting frame into a recovery trajectory. The cutter rolled beneath Continuity's dorsal bay and fired two tow lines through the service boats' bow eyes. Cruiser deck crews joined the boats with a third line so their thrust could not separate them.

The first boat cleared under docking jets. Its tow snapped taut and pulled Senn's cutter three degrees off the verified lane. The second emerged before she corrected. Both boats swung behind her across a lens image of the cruiser's own bow.

"Train clear," Senn said.

Eighty-three names moved from cruiser roster to boats. The cutter carried no spare acceleration margin now. It would follow Continuity into the first fold and peel away before Node Three.

Halvek restored the beam coolant tanks to the placement plan. Nobody called the solution free. Senn had discarded hardware and accepted a worse escape burn. Irian's fuel train retained its reserve. Four hundred twelve people still had a path that did not require the cruiser to survive.

Chief engineer Mera Vos refused the first transfer order. Her face appeared briefly on the shared roster channel, lined by decades in engine heat. "The ballast sequence needs my hand," she told Halvek.

"Your deputy has the sequence."

"He has six months in this hull."

"Then he has six months more than the tug crews receiving you." Halvek released her console permissions while he spoke. "Transfer the knowledge from the cutter. Go."

Vos looked toward someone beyond her camera. "You taught us that abandoning route hardware abandoned everyone depending on it."

"I taught you to confuse hardware with continuity."

The admission did not ask forgiveness. It arrived as an operational correction, late and costly. Vos stripped a diagnostic ring from her wrist and locked it around her deputy's arm. Then she joined the line at the dorsal bay.

A mess worker carried two sealed casualty books under one arm. Another crew member tried to bring the cruiser crest, a metal plate too large for the cutter hatch. Senn's officer made him leave it against the bulkhead. They saved reactor logs, personnel rolls, hold-command archives, and the local copies of Halvek's suppressed model. Nobody saved the emblem.

The final galley team crossed with food packs clipped to their suits. Even under evacuation, someone had counted what the receiving cutters could feed. Kessa understood why Irian kept logistics officers near every moral decision. Survival continued to arrive in containers, and abandoning a ship did not excuse abandoning the next meal.

At three hundred remaining, the first shear fold caught Continuity's bow.

The cruiser stretched on visual display. Its hull instruments disagreed by sixty metres. A military autopilot would have corrected against the apparent bend and broken the ship. Halvek ordered manual thrust from local accelerometers. The bow came through.

At one hundred twelve, a launch jammed in the dorsal bay.

"Bay collar distorted," a watch officer reported. "Forty-three aboard."

Sena marked Threadbare toward them.

Kessa stopped her. "We leave Node Five, the wounded juvenile loses its open gradient."

"I know."

A neutral cutter reached the bay first. It could not dock, so its crew fired two grapples through the launch's emergency eyes and tore the collar outward. The launch came free trailing insulation and half a door. It rolled into the cutter's exclusion cone, close enough for both ships' alarms to merge.

"Launch clear," Senn said. "Seventy-nine remain."

The lens edge reached Brine's outer service web.

Metal trusses bent in apparent arcs. One transfer spindle parted, its fragments following separate trajectories without striking a habitat. Kessa had minutes before the agricultural cylinders entered the same slope.

"Continuity, light your port beams at five percent," she said.

"Port five," Halvek answered.

A faint red fan crossed the dark. It did not touch the adult or Sable's juvenile. It

pressed against the open side of the moving topology, offering a shallower path away from the orbital plane. The lens edge slowed.

"Ten percent. Roll seven degrees."

The cruiser rolled while evacuation craft detached. Its broadside entered Node Three. Loads climbed across its frame.

Pell read the numbers. "Keel differential past design."

Halvek said, "Design assumed fixed space."

"Steel does not care what design assumed," Kessa replied. "Hold nine percent and vent your starboard ballast."

Water, shielding pellets, and reserve propellant streamed from Continuity. The released mass spread through the node, each fragment creating a small correction. Brine's lens edge stopped three kilometres above the service web.

Eleven juvenile signatures reached middle release.

Kessa called them one by one. Nacre. Brine. Tern. Orison's three. The dead route's survivor. Four anchors whose names had once meant only destinations. Every routekeeper team confirmed contraction before allowing the next topology to open. No command propagated automatically. People read local loads and waited when the animal timing required patience.

Sable continued to lag.

Its signature fluttered outside the adult's ventral fold. Scar tissue from the doubled hold had closed in the wrong order. Each pulse drew it forward; each damaged outer layer pulled it back. The adult's topology widened around the absence, extending the dangerous edge toward Brine again.

Anu's voice tightened. "It cannot reach core release while that outer scar carries load."

"Can we cut the scar?"

"Not at this distance. A beam would worsen it."

Kessa looked at the net. Node Five, where Threadbare held position, sat between Sable and the adult. The tug's mass could not pull the juvenile. Its cold-shear cutter could act only within metres. No ship could cross the changing lens, cut living filament, and leave before the trough.

Tomis's torque key knocked against the console.

Three soft contacts, driven by the pulse through Threadbare's frame.

Kessa took it in her scarred hand. The tool had carried Lark-3's hidden log because its obsolete cavity escaped Charter cleanup. It had opened compressor housings, cage panels, and one truth she had accepted too late. Now its brass length gave her a better instrument than the timing display. The display averaged eleven arrivals. The key transmitted the local load under her palm.

"Sable does not need a cut," she said.

Anu answered at once. "Explain."

"The scar closes out of order because it never gets a full contraction wait. Every net correction pulls the outer layer during the pause."

"We remove Node Five and lose its path."

"We don't remove it. We go dark between beats."

Sena saw the maneuver. "Ballistic for two point six seconds."

Pell said, "Adult edge crosses us in two point two."

"Local measurement?" Kessa asked.

"Node Five local."

"Then two point two means ours."

Kessa sent the plan to Anu and waited through a silence measured by loads. Anu checked Sable's regeneration trace. "It could contract. No certainty it will."

"Nothing in this net came with certainty."

"Do it on the next pulse."

Behind them, Continuity began to fail.

A beam port tore from the cruiser's dorsal spine. Red light swung across empty space before the system shut down. The hull lost fourteen percent of its stabilizing output. Brine's lens edge started moving.

"Marshal, evacuation count," Senn demanded.

"Six on the bridge. Eight in engineering. My cutter has room."

"Then leave."

"The final beam sequence needs a local release."

Kessa checked his controls. Damage had severed remote command. Someone had to discharge the beam capacitors in order, or their fields would collapse together and kick the adult's open fold toward Brine.

"How long?" she asked.

"Forty seconds after node lock."

The cruiser might last sixty.

Senn said, "I am docking now. Four of my people will hold your bridge."

"No," Halvek replied. "My order built these capacitors into a hold system. I know the release lags."

"You are preserving your trial, not choosing your monument."

For once, Halvek did not argue capacity. "Dock and keep engines live."

Senn's cutter attached to the ventral port while engineering crews crossed by pressure sleeve. The six bridge officers followed. Halvek remained at local beam control under the eyes of two arrest officers positioned inside the cutter hatch.

Kessa returned to Sable's pulse trace.

"Node Five prepare dark," she said. "All other nodes hold current gradient. Do not compensate for us."

Sena killed automatic thrust. Pell isolated the sighting transmitter. Vasken released both grapple drum brakes so no stored line load could imitate a correction.

The first beat came through the key.

Kessa counted the rise, not the sound.

At the second beat, Sable's outer scar tightened.

"Dark now."

Sena cut every engine. Threadbare became eighty-three metres of uncommanded mass inside a changing lens. False stars swept the cupola. The adult's edge reached for them in six luminous images. Kessa kept her hand on the key and felt the juvenile's scar unload.

One second.

Two.

A smaller tremor arrived between pulse beats. Sable had contracted.

"Middle layer opening," Anu said.

Kessa waited. Every reflex demanded thrust. The tug rolled without permission. Somewhere aft, loose tools struck a wall.

The third beat entered her palm.

"Core triad now. Light Node Five."

Sena fired. Threadbare's mass pressed into the gradient just as Sable's compact topology opened. The wounded juvenile moved without snapping. Its scarred outer folds trailed unevenly, then settled into the wake made by the other eleven.

The adult matched them.

All twelve signatures crossed the same pulse trough.

Its topology unfolded beyond the scale of Kessa's board. The dangerous edge lifted from Brine's plane. Juvenile wakes braided into the adult's moving body. No voice thanked them. No choice resembling human mercy shaped the departure. An injured animal had found the gradient its life required.

"Node lock," Halvek said.

On Continuity, he began the final discharge. Eight remaining beams dimmed in sequence. Each loss transferred more load into the hull. The cruiser buckled around its central truss. Armor plates peeled away and followed the wake.

Senn shouted through the open hatch, "Enro, move."

The seventh beam went dark.

Halvek left the control frame. His suit camera showed him crossing a bridge tilted by structural failure while two arrest officers covered the hatch. He jumped the final gap as the pressure sleeve tore. Senn fired her cutter free before the hatch sealed.

The ninth capacitor discharged inside the cruiser.

Continuity held Node Three for another four seconds as dead mass. Those seconds carried the adult's ventral fold clear of Brine. Then the cruiser entered the shear.

Its bow and stern took different roads. The central truss opened. Reactor vessels separated under automatic scram, dark and intact, while the rest of the ship flattened into a widening curve of metal. No explosion provided a clean ending. The strongest movable hold in the Reach became fragments too dispersed to pin anything again.

Senn's cutter emerged beyond the fold trailing atmosphere. "Enro aboard. Arrest remains in force. Six injured, no fatalities on final evacuation."

Kessa closed her eyes for one breath. Saving the crew did not restore the dead at Tern, Orison, or Sable. Destroying the instrument did not erase the orders issued from its bridge. Halvek had survived to meet names, evidence, and judgment.

Across the chain, fixed routes collapsed.

Anchor mouths narrowed at Nacre, Brine, Tern, Orison, Sable, and seven distant stations. Resonator crews powered down arrays that no longer contained hollows. One by one, the approved green corridors vanished from every navigation slate. Seventy-three routes across the Reach did not all fail that hour, but the connected economy built on captive juvenile bodies had ended. No safe sequence could make the old arrangement harmless.

The adult moved outward with twelve smaller distortions gathered along its wake. Shed fibers glimmered behind the molt, thin enough to bend single stars instead of whole fields. Anu recorded them without naming a use.

Kessa watched until the final juvenile signature passed beyond the Net.

No instant corridor opened in its place.

The beams shut down. Tug drives fell quiet. Straight stars returned where the adult had occupied the sky, unfamiliar because no cage doubled them into useful arcs.

Threadbare drifted in true dark among the scattered ships.

Beneath Kessa's hand, Tomis's torque key lay still.

Chapter 27 — What Travel Costs

The relief ship arrived with frost over its name.

Seven months of fusion burn had sanded paint from the bow and driven coolant ice into every seam. Common Measure entered Brine on a plume the color of old copper, too slow to make spectacle and too heavy with cargo to waste thrust on grace. Irian watched from the logistics gallery of Accord of Dust while four local tugs eased toward it.

No route mouth delivered the ship. No doubled stars promised safe geometry. Its crew had crossed ordinary dark from Nacre with an engine, stored reaction mass, and patience measured in consumed parts. The first light from its departure had reached Brine long before the vessel.

A controller beside Irian wrote on a paper board: MONTH 7, DAY 203.

The date mattered because every report from the old route economy still wanted to compress the journey into an arrival code. On those forms, delay occupied one box. Here, delay had eaten seed reserve, separated families, and turned medical inventories into lists of names.

“Range one thousand,” the tug lead called. “Target rotation two tenths high.”

Common Measure answered after the brief local transmission lag. “We can stop rotation or preserve pump power. Choose.”

“Preserve pumps,” Irian said. “Tugs will take the mismatch.”

Her order traveled through Brine control, not a convoy command circuit. She held no centralized helm now. Accord still carried 398,000 evacuees and much of the surviving infrastructure; twelve thousand had remained in provisioned Brine shelters under the Articles. Local councils, ship captains, passenger delegates, and routekeeper cooperatives shared decisions because no single hull could supply everyone.

That arrangement consumed time.

It also caught mistakes before they became fleet policy.

The tug lead acknowledged. Two agricultural cylinders objected to the docking vector because exhaust contamination threatened open algae radiators. A machine shop offered a colder approach. Brine's council approved the change after checking habitat loads. Nine minutes passed before anyone fired an engine.

Seven months earlier, Irian would have called those minutes intolerable.

Now she counted the radiators that remained clean.

Marl Quade entered the gallery carrying three ration slates and a cup of something grown to resemble coffee by people who remembered the word better than the taste. “Inquiry wants you in twenty minutes.”

“Ship docks in forty.”

"They know."

"Then they know which one I attend."

Marl set the cup near her hand. "Remote testimony. You can do both badly."

Irian looked at the slates. "Which habitat?"

"Dross Lantern missed protein yield again. Pell Orchard has spare fungal stock but wants machine hours in exchange. Sable Ring Refuge Three stopped answering yesterday."

That last line carried no explanation. Communication between systems traveled by courier ship, tightbeam when geometry allowed, and wake-fiber relay experiments that failed more often than they worked. A habitat could stop answering because its transmitter broke. It could also stop answering because no one remained awake to use it.

"Last confirmed inventory?" Irian asked.

"Twenty-six days of air catalyst. Eleven of full ration. Surface elevators at Sable promised a launch if ring debris cleared."

"Promised when?"

"Six weeks ago."

Irian wrote Refuge Three beside the cargo allocation for Common Measure. Medical catalyst, pressure seals, compact food substrate, reactor control mesh. Everything she assigned there came away from people she could see.

Survival reports occupied three screens because any single total hid which reserves had failed.

Nacre had reopened three fabrication belts and lost two mining settlements when spare heat exchangers failed. Brine had avoided famine by dividing food substrate among ships before the routes collapsed, yet every cylinder ran below preferred nutrition. Sable's surface cities housed most of the 31,000 displaced from orbital structures. Smaller habitats beyond the old chain endured alone. Some built local fusion craft from station drives. Some dismantled their anchors for metal. Two had gone dark.

Brine's protected child rations and Sable Refuge Three's empty catalyst stores occupied separate lines on the same allocation board.

During Month 2, Brine had cut every adult ration by nine percent and protected children's protein allotments. Month 3 brought the first local harvest from machine seed distributed across the convoy before the crossing. Two batches failed because their host ships could not hold humidity. Five produced enough culture to cover the loss. By Month 4, workshops had standardized six pump parts that once came from separate systems. None matched the old parts' service life, but mechanics could make them without waiting for a route cargo.

Slow fusion convoys began as promises on planning boards. A courier from Sable departed with ring ceramics and three passengers. Brine sent food culture

toward Nacre. Nacre assembled Common Measure from a survey tanker and two freight spines because no purpose-built carrier could be spared. Every departure removed engines, technicians, and fuel from the place sending help. Every arrival depended on the destination preserving stores for a ship it could not hurry.

Some settlements refused the exchange compact. One mining habitat kept its reactor mesh and declined Brine culture because its council expected the old routes to reopen. Another launched too early, lost a drive bell, and spent eleven weeks limping home. The public boards carried those failures beside successful departures. Hope could waste fuel as effectively as panic if nobody printed the margins.

Irian had learned the names of the dark habitats. Lattice Home, population six thousand, last message a request for valve ceramics. Sable Refuge Nine, population eleven hundred, transmitter active but life-support load unreadable. Narrow Glass, a factory spindle with enough power and no seed culture. She assigned courier mass by survival probability and hated the phrase each time. Probability did not breathe inside a failing room. It only told distant people where limited cargo might arrive in time.

"Give Dross Lantern the fungal stock," Irian said. "Pell Orchard gets machine hours from Accord's aft works. Add a maintenance crew to Refuge Three's package and put the allocation before delegates."

Marl studied her. "You could authorize emergency release."

"I could. Then every settlement farther than my eyes becomes easier to spend."

"You have learned to make us late."

"I had excellent teachers."

Marl took the slates to the delegate channel. Irian drank the false coffee and watched frost stream from the relief ship's bow.

A hearing pane opened beside the range plot.

The public inquiry met aboard three locations at once: a chamber on Nacre, a converted food hall at Brine, and a sealed evidence room on a neutral cutter. Its members included routekeepers, passenger delegates, Charter jurists without command authority, habitat engineers, and families of the dead. The inquiry could name facts and recommend charges. Halvek's trial would come later if enough courts survived to hold one.

Irian's image joined the Brine hall. Condensation marked the wall behind its commission table. Half the seats had once belonged to vat technicians during shift meals.

Chair Vael Rusk spoke without ceremony. "Captain Mott, we are examining the decision to maintain and intensify holds after the amplification model became available on Day Twenty. Do you affirm your submitted operations log?"

"I affirm the log and its corrections."

“Did Marshal Halvek Enro provide the model to your convoy command?”

“No.”

“When did you learn it existed?”

“After the Sable lensquake.”

The chair placed two documents on the public record. One showed Halvek's suppressed analysis. The other carried Irian's requests for stable routes during the same period.

“Your requests argued that closure would threaten 410,000 evacuees and 70.4 million tonnes of essential freight,” Rusk said. “Do you withdraw that claim?”

“No. It remained true.”

A murmur crossed the Brine hall.

Irian kept her attention on Common Measure's docking marks. “Our dependence did not make the holds safe. It made disclosure more urgent. We needed the amplification model to choose among costs. Halvek chose for us by hiding one side.”

A routekeeper commissioner leaned toward his microphone. His union badge carried the old nine-station wheel with a black line cut through it. “Route crews also knew cages injured the structures before Day Twenty.”

“Kessa Rho's evidence established injury by Day Six,” Irian said.

“Did you stop using corridors then?”

“No.”

“Why not?”

“Because a hospital cylinder and several hundred thousand people occupied a divided route. Because I believed use could continue while release methods developed. Because I counted the immediate stranded ships more clearly than the animal carrying the road.”

The commissioner did not rescue her from the answer. “Would you make the same decision now?”

“No. Knowing what I know now changes the available choice. Claiming otherwise would turn hindsight into a performance.”

The inquiry entered her answer without comment.

Recovered Charter archives gave the inquiry three findings it could enter without repeating every witness. Responsive filament had appeared in reports for a century. Nacre supervisor Orra Dane had signed twenty-six records that recoded scars as self-sealing seams after an early biological finding cost her crew its contract. The commission placed her signatures beside photographs from the dead adult and kept her admission that she had trained apprentices to use the same codes.

Irian submitted her Day Eleven triage board with three civilian modules marked

for possible jettison. Her refusal and her staff's preparation remained on the same page. Passenger delegates added the Brine food demand and the phrase nonessential mass as evidence that disposal language had traveled through shipping law before Halvek used it.

The command record carried narrower authority. Halvek had received the amplification model, suppressed it, ordered the remote hold at Brine and the seizure at Orison, then left Sable to apply a reinforcement protocol beyond certified limits. His famine history explained his choice. His signatures fixed responsibility for it.

Rusk changed the evidence feed.

Halvek appeared under guard in a small cabin aboard Mica Hand. He wore no uniform jacket. One wrist carried a movement cuff linked to the cabin hatch. The frame showed Captain Orra Senn seated outside his reach, representing neutral custody.

"Marshal Enro," Rusk said, "do you affirm that the amplification model reached your bridge on Day Twenty?"

"I do."

"Did you suppress external distribution?"

"Yes."

"State your reason."

Halvek looked older without Continuity around him. "The model predicted systemwide collapse under continued full holds. Immediate release also stranded famine relief, medical shipments, and inhabited modules. I believed staged holds could buy time for evacuation."

"Did the analysts certify that belief?"

"No."

"Did you inform affected systems of uncertainty?"

"No."

"Did you order coercive action against ships refusing holds?"

"Yes."

The chair let each answer settle into the public record.

A Sable family representative received the floor. She gave her name as Oren Tev and identified two dead route workers: her wife, Lio, and their eldest son, Per. Both had remained on the orbital ring under Charter orders during the doubled hold.

"You came to Sable after the ring broke," Tev said. "Did you know their names then?"

Halvek did not look away. "I read them on the casualty list."

"You used Continuity to save Brine."

"Yes."

"You evacuated its crew."

"Yes."

"My family did not receive that option."

"No."

The single word carried no request for absolution.

Tev placed a maintenance photograph into evidence. Two people stood beside a resonator port in work suits, one holding a graphite inspection stick. "Your final act saved lives. I am told I must say that if I want an accurate history."

Rusk said, "You are not required to praise him."

"I am not praising him. I am refusing to make accuracy another thing his office owns." Tev faced Halvek's image. "You saved people at Brine. You helped kill mine at Sable. The same record can carry both."

Halvek lowered his head once. "It must."

Irian felt no relief. A clean villain would have offered it. Halvek remained the man who had fired through a habitat exclusion cone and the man who stayed aboard a failing cruiser until his crew escaped. Preserving both facts denied him a hero's erasure and denied everyone else the comfort of pretending only monsters had maintained the routes.

Before recess, the commission entered provisional findings of material suppression and unlawful beam use. It referred Halvek's command acts to civil trial, froze the Charter's surviving indemnity reserve for Sable and Orison claims, and ordered all recovered anchor designs copied to public fabrication archives. Three legal entries changed who controlled money, evidence, and repair work before any final verdict.

The reserve freeze interrupted two pending cutter-refit contracts before Rusk finished reading the order. Their metal allotments moved to Sable pressure trusses, with every transfer published against a claim number. Irian watched the first six entries arrive and recognized consequences no testimony could postpone.

The inquiry recessed when Brine control called final approach.

Irian closed the pane. Halvek would remain under arrest until trial. The commission would continue collecting claims from settlements whose couriers had not yet arrived. No verdict could travel faster than the people and evidence carrying it.

Common Measure filled the gallery window.

Its scale arrived gradually: first a bright drive point, then a scarred bow, then cargo spines extending behind the central tankage. Patches covered the forward radiator. One section bore bare metal where micrometeoroid shielding had been

moved to protect the crew drum.

"Manifest confirmation," Brine control said.

The relief ship transmitted its cargo in blocks. Air catalysts. Water membranes. Fungal cultures from Nacre. Sable-manufactured bearing ceramics loaded before departure. Medicines compounded aboard during cruise. Letters, legal records, school archives, repair designs, and three passengers who had spent seven months traveling to rejoin families.

No single cargo solved the Reach.

Every item closed one gap while another remained open.

The first relief convoy carried scarcity with it. One coolant pump had failed during the burn, forcing the crew to thaw reserve shielding ice. A crop vault overheated before they isolated the compartment. Twelve tonnes of protein culture arrived dead, and three medical compounds had lost certified temperature history. Irian ordered those containers marked unusable until Brine laboratories tested them. Need did not make contamination nutritious.

Delegates watched the manifest deductions in real time. Dross Lantern's requested allotment fell below its next growth cycle. Pell Orchard offered half its own stock without asking for extra machine hours. A Nacre engineer aboard Common Measure found a substitute medium among the ship's waste cultures. It yielded less protein but required no seed reserve.

"Publish the process before transfer," Irian said.

The engineer blinked at her through the cargo feed. "It is not validated outside our reactor loop."

"Publish that too."

Under the Charter, a useful process would have entered a licensed route package and traveled with payment restrictions. Brine's council placed the substitute medium on the open fabrication board within the hour. Three habitats rejected it after reading the heat requirements. Two began test batches. Nothing became universal because someone in authority wanted a single answer.

The relief convoy also carried people Brine had nearly stopped expecting. A pressure technician from Nacre found her husband assigned to an algae cylinder. Two sisters from Sable arrived with separate copies of the same family archive in case one ship failed. Their reunions occupied no cargo column, yet passenger delegates had reserved berth mass for them through every ration debate.

The tugs caught Common Measure on four lines. Its rotation transferred into their frames. Two lines climbed, one slackened, and local pilots corrected by load rather than visual alignment. Irian watched people perform the same work that had carried the crossing, now without a veilback's wake distorting space. Ordinary docking had become slow enough to reveal its own difficulty.

"Outer cargo spine secure," a controller said.

Brine's delegate council approved the first distribution. Refuge Three received catalyst and seals. Dross Lantern received fungal stock. Two distant cylinders received less than requested because Common Measure had consumed part of its reserve during an engine repair. The shortage entered the public ledger beside the reason.

Irian left the gallery for the receiving lock.

Marl met her there with a group of children from Brine's communal school. They had been chosen to carry welcome packets because adults understood how easily a ceremony could become a speech. Each packet contained local maps, ration rules, and names of the people assigned to help the arriving crew.

The inner hatch opened.

A woman in a grease-dark flight suit crossed first. Frost melted from her boots and ran across the deck in silver beads. She had shaved one side of her head around a healed burn. Behind her came two engine workers supporting a man whose muscles had weakened during the long burn.

"Captain Mott?" the woman asked.

"Locally."

The pilot almost smiled. "Captain Sia Neral, Common Measure. Nacre sends forty-one tonnes less than promised, six weeks later than promised, and with more apologies than requested."

"Brine accepts the cargo. We will inventory the apologies before distribution."

Marl handed Sia a welcome packet. The first child offered another to the injured engineer and asked whether the frost came from outside the ship.

"From our own coolant," he said. "Outside does not give you much for free."

The child considered this. Her name strip read ALI QUADRE, AGE 9. She looked past the crew toward the scarred hull in the docking collar.

"My grandmother says Nacre used to take three hours," Ali said.

Irian remembered corridors opening like certainty. Three hours had hidden resonator crews, scarred juveniles, hold commands, and the assumption that distance should submit because people had cargo to move.

"It did," she said.

"How long does it take now?"

"For Common Measure, seven months."

The child frowned at the number. "How long will the next journey take?"

Irian looked through the lock window at workers carrying catalyst cases one by one. Beyond them, the relief ship's frost loosened in clear fragments under Brine's lamps.

"If the engines hold, six months and twelve days," she said. "If they do not, longer. We will know where it is because they will tell us, and we will keep supplies

until it arrives.”

Ali nodded, not pleased and not deceived.

On the dock, someone chalked the next departure date beneath the arrival board.

Chapter 28 — The First Slow Ship

Kessa found the bad load forty minutes before departure.

It hid in the port shear vane where a new ceramic collar met an old tug bearing. The instrument called the mismatch acceptable. Her glove called it a cracked mount waiting for thrust. She braced one boot against the service rail of the small ship and put Tomis's torque key on the inner bolt.

The brass handle had lost more plating in three years. Its obsolete diagnostic cavity now held a wake-fiber calibrator no longer than Kessa's thumbnail. When she applied pressure, the key translated the vane's tiny gradient into three tactile pulses.

Two arrived clean. The third dragged.

"Port collar," she said.

Sena's voice came from inside the hull. "We replaced it yesterday."

"We replaced the wrong part yesterday."

"That improves morale."

Kessa loosened the mount. Beneath it, a graphite shim had split along the manufactured grain. Ordinary damage, not strange biology or hidden Charter code. She felt almost affectionate toward it.

The ship rested in Brine's outer construction dock, thirty-one metres of fusion drive, pressure cabin, instrument truss, and six folding shear vanes. No cage surrounded it. No resonator beam touched the dark. Far beyond the dock, one faint star bent around a wake fiber shed during the veilback molt three years earlier.

That curve marked their path.

Year 3 after the molt had begun with unmanned tests. Routekeepers pushed instrument cans into fibers and recovered half of them. The first vanished when a decaying edge rolled across its drive clock. The second came back with every exterior fastener loosened in the same direction. A third crossed four million kilometres, transmitted useful load maps, and burned during an ordinary engine fault after leaving the wake. The public report separated the wake result from the engine loss.

Kessa had flown the fourth can from Threadbare by remote grapple. It entered Coda-Seven, gained a fraction of effective velocity, and came out with less fuel than a conventional burn required. No signal passed along the fiber ahead of it. No filament closed around the probe. Anu found no stress variation resembling the migration response. Six more tests repeated those results before anyone proposed carrying people.

The first crewed proposal failed its own review. Its designers had added a low-power resonator to widen the thread around the hull. They called the device a

stabilizer because nobody wished to print the word hold. Kessa placed the field diagram beside Nacre-9's old cage geometry. The project council rejected it, published the reason, and dismantled the coil under open cameras.

Construction resumed with vanes that read and rode gradients rather than imposing them. That choice enlarged the fusion drive, reduced useful cargo, and doubled the estimated crossing time. It also gave a weakening fiber permission to refuse them. If the wake faded, the ship would fall back into ordinary space and continue slowly under its own power.

The first fixed routes had carried ships between systems in hours. The vessel under Kessa's boots might reach Nacre in six weeks and four days if the fiber held its measured decay. If the thread weakened early, ordinary fusion burn would add eleven weeks. If the drive failed after midpoint, a rescue ship could take months to reach them.

Every passenger had signed those numbers without a promise attached.

Anu floated out through the service hatch with a specimen case strapped to her chest. At thirty, she had acquired more institutional titles than patience. Her suit still carried the plain green stripe of gravitational ecology.

"Please tell me you are not teaching the calibration key nostalgia," she said.

"The key found a cracked shim."

"The strain mesh found it yesterday."

"The strain mesh approved it."

"It marked one point eight percent outside nominal."

"On a mount with one percent room."

Anu pushed closer and examined the split. "Then the installation model approved it. The mesh behaved correctly."

Kessa handed her the broken shim. "You can explain that distinction to the vacuum."

Sena emerged behind Anu carrying a replacement collar. Her hair had gone silver along one temple since the crossing. She had rejected three offers to captain larger ships and accepted ownership in this one only after the cooperative removed a clause giving Brine exclusive control of departure data.

"Found this in the first crate," Sena said. "It has an ugly edge."

"Ugly fits."

Together they replaced the shim, seated the collar, and checked the load again. Three crisp pulses traveled through the torque key. Kessa saved the reading to the public departure log.

Within seconds, six other docks copied it.

Every measurement from the slow ship went out openly: vane geometry, wake decay, failed materials, crew dose, fuel use, correction burns, and the equations

Sena distrusted enough to test by eye. Nacre had built a sister craft from the same plans. Sable had changed the vane hinge and published the improvement. Two private carriers offered to fund faster prototypes if the cooperative delayed release of new data. The offers remained in the public archive beside the refusals.

No monopoly owned the fiber.

That rule had made construction slower. It had also produced twelve independent checks on the port collar.

The argument over ownership had nearly stopped the ship. Brine supplied dock mass and wanted priority passage for food cultures. Nacre supplied drive ceramics and wanted control over copied engine plans. Sable's rebuilding council wanted guaranteed berths for ring technicians. Former Charter offices offered navigation archives in exchange for a licensing role.

Marl had convened the dispute in the same food hall used by the inquiry. Kessa attended long enough to explain that wake data changed while lawyers spoke. Sena displayed three independent vane designs. Anu read the biological prohibition into the record, then refused every amendment that weakened automatic publication.

The final cooperative gave builders passage priority only on the ships they physically supported. No system could restrict plans produced with shared measurements. Safety objections entered the public archive with names and evidence. A private builder could improve a design and charge for the hull, but the wake itself generated no property claim.

Routekeepers carried much of that rule into practice. Thousands had lost cage contracts when the fixed routes ended. Some became fusion mechanics. Others dismantled resonator stations for usable metal or staffed the long-baseline observatories that tracked fading fibers. A few refused the new work and petitioned to reopen empty cages, arguing that no juvenile remained to harm. Anu's surveys showed residual living filaments at four sites. Even where none appeared, the cooperative rejected rebuilding infrastructure designed to capture the next migration cycle.

Kessa had voted with that refusal. She also knew what it cost. Tomis learned his trade because route work paid enough to support a family. Removing harmful machinery did not create harmless wages. The slow-ship yards survived only because Brine, Nacre, and Sable treated navigation as shared infrastructure rather than a salvage market waiting for ownership.

Kessa entered the ship through the service hatch. Threadbare had given up its cold-shear cutter, one grapple drum, and much of its manual console to build the vessel. The old tug remained at Brine as a repair ship with a patched rail where the first filament had grown through it. Kessa had refused to turn the scar into a display. Vasken stored spare line there.

The new cabin carried eight people. Four were routekeepers. Two maintained

the fusion drive. Anu owned biological limits but no authority over navigation. Sena flew. Kessa handled wake loads and exterior repair. Nobody held a title broad enough to decide alone.

Pell had stayed with Threadbare. He claimed slow travel required younger joints and then sent thirty-seven pages of instrument warnings.

Kessa strapped into the work seat behind Sena. The console used brass levers beside modern field displays because hands remained useful when local clocks disagreed. Tomis's key fit into a calibration slot at Kessa's right knee. Its handle protruded far enough to catch a careless sleeve.

Sena looked at it. "We could build a proper connector."

"We did. It drifted."

"We could build a proper connector that does not drift."

"Put it on the list for Nacre."

The departure board showed twenty-three unresolved objections. Most concerned acceptable wake decay. One came from a Sable insurer that wanted the voyage classified as experimental freight movement rather than passenger service. Marl Quade had answered by publishing the insurer's own loss assumptions with their arithmetic corrected.

The remaining objections belonged to people who had signed passage and retained the right to change their minds until the outer lock closed.

Kessa opened the crew circuit. "Final withdrawal check. Speak to Sena on private if you want off. No cause required."

No one spoke publicly.

Sena waited the full five minutes. One engine worker requested private channel. Kessa watched his status change from green to amber while they talked. He had a daughter on Brine and a partner traveling on the second slow ship. Departure would separate them for at least a year if schedules failed.

His status returned green.

Sena said only, "Eight aboard."

Consent did not become permanent because someone had counted it once. They would ask again before entering the fiber, and at every point where ordinary thrust still offered a safe turn.

Anu opened the wake display. "Fiber Coda-Seven has lost three percent coherence since yesterday."

"Model allowed five," Kessa said.

"Model also expected symmetrical decay. Port edge has thinned faster."

Sena rotated the projected path. "Can we ride starboard?"

"We can enter starboard. The fiber may roll us inward after the second gradient peak."

Kessa enlarged the raw observations. Most local wake fibers had faded within months. Denser strands propagated along the old molt corridor as slowly moving gradients, and Coda-Seven's navigable segment had reached Brine eleven weeks earlier. It contained no juvenile. Anu's probes found shed baryonic filaments and decaying topology, closer to a trail of skin and altered gradient than a living body. Navigation disturbed it slightly, but no response propagated back toward the departed animals.

The first specimen cut from Nacre-9 had remained in Anu's archive. Within weeks of the nine-minute dark, its folded strain collapsed into inert carbon and silicate dust. The archive kept that dust beside its complete load record and permitted no new culture attempt.

Coda-Seven's measured decay and lack of organized regeneration justified one monitored passage, not ownership.

Anu had made Kessa repeat the evidence standard at every review. Shed fiber lacked organized regeneration. Its gradient decayed without a pulse cycle. Samples did not contract around damage or alter course toward the adult's departed wake. Their instruments could still miss forms of response they did not know how to detect, so absence of evidence granted no permanent clearance.

Each slow ship carried withdrawal probes ahead of its vanes. A probe sent load changes backward through physical cable rather than interpretive software. If a filament closed, a recurring three-part rhythm appeared, or decay reversed near the hull, the cable cutter fired and the ship burned away. All three events remained unknown. Those stop conditions entered the flight charter before any departure approval.

"Coda-Seven probe still clean," Anu said. "No organized response across sixty-two hours."

Kessa checked the raw trace. Random tremors followed thermal changes in the cable. One broad load matched a distant cargo tug crossing behind the fiber. Nothing resembled the patient pressure she had felt through Nacre's grapple line.

"Publish the tug correlation," she said.

"Already attached."

Their caution could not prove innocence. It could only remain visible enough for someone else to stop the work when evidence changed.

Anu had written limits into the cooperative charter. No craft could strengthen a fiber with a hold beam. No navigator could conceal biological response. Any recurring pulse required immediate withdrawal and public review. Wake-shear travel would remain slow or cease.

"Use the outer third," Kessa said. "Lower gain on Vane Six. If the roll exceeds two degrees local, we leave the thread."

"Which local?" the engine worker asked.

"Yours at the drive, mine at the vane, Sena's at the hull center. Any one can call withdrawal."

He nodded and copied the rule onto his manual slate.

A dock alarm announced visitors at the inner lock.

Irian entered with Marl and two Brine technicians carrying a case of water membranes. Three years had drawn more gray through Irian's hair and removed the convoy insignia from her jacket. She now chaired a rotating transport council when local delegates could not find someone else to blame. Accord of Dust had become a settlement spine, its great engines used only for orbital adjustments.

"You are eight hundred kilograms over filed departure mass," Irian said.

Sena pointed at the membrane case. "You brought two hundred of it."

"The other six?"

"Open instruments from Sable," Anu said. "They arrived late."

Irian looked at Kessa. "Your margin?"

"Enough if we cut ten days of ceremonial food."

Marl opened a storage panel and removed a sealed Brine cake. "This object has threatened three committees. I volunteer it."

Sena took the cake from him. "Denied. Ballast has navigation value."

The exchange relieved no real risk, which made it useful. Crew shoulders lowered. Irian checked the manifest herself and found two duplicate tool kits. One returned to the dock. The membranes stayed.

Beyond the lock, departure workers began clearing the service gantry. Brine's cylinders turned beneath the red dwarf. New workshops occupied trusses once reserved for route cargo. Slow ships in several stages of construction dotted the outer docks. None shared exactly the same vane layout.

Kessa guided Irian to the instrument truss.

A sealed copy of the route inquiry occupied one archive block. Halvek's public trial record had arrived from Nacre by courier the previous year. He remained alive in custody, stripped of Charter office, with his testimony, convictions, and final evacuation orders preserved together. No annotation called the loss of Continuity repayment. Sable families had objected to that language, and the archive kept their objection beside the judgment.

Irian touched the archive status light. "You carry the whole record?"

"Every slow ship does."

"Redundancy?"

"Distrust."

"Better word."

They moved forward to the cupola. The dock framed Brine in metal ribs. Without

an anchor, its stars held single positions.

Irian inspected the scratched rim taken from Threadbare. "You kept the worst piece."

"It already fit."

"You could wait for the Nacre craft to run first."

"Nacre could wait for us."

"I know." Irian rested one hand on the cupola frame. "I still had to ask."

Kessa understood the count behind her face. Eight aboard this ship. Thousands depending on its measurements. Six weeks if the wake held. More if it did not. Irian had spent three years converting distance into stores and schedules. She had not learned to like any number merely because people consented to it.

"Brine has enough culture through the next arrival," Kessa said. "The second ship can reach us inside three weeks after a failure call. We carry independent burn for the full crossing."

"I have read your filing."

"You corrected the food line."

"It needed correction."

They stood without finding a larger statement worth making. Kessa remembered meeting Irian outside Nacre during an emergency transfer, when six hours seemed like generosity and a closed route looked like the whole danger. Respect had grown between them through refusals, bad margins, and work neither could finish alone. It required no different name.

Irian held out her hand.

Kessa looked at it. "Inspection?"

"Goodbye."

They clasped wrists because gloves made palms awkward.

"Send your first load table before you send impressions," Irian said.

"Tell your council not to average it."

"They will. I will make them print the raw values underneath."

"Close enough."

Irian released her and left with Marl. At the hatch, Marl reclaimed the Brine cake from Sena's ballast rack and carried it onto the dock under protest.

The lock sealed.

Departure clearance arrived from Brine control, Nacre observation, Sable tracking, and the passenger cooperative. Four approvals, none sufficient alone. Sena fired cold maneuvering jets and lifted the vessel from its cradle.

The dock fell away at walking speed.

Kessa felt each clamp release through the hull. Forward pair clean. Aft port delayed half a second. Instrument truss free. No hidden load followed them.

The ship had acquired a name during construction: Patient Distance. Kessa had voted against it because distance did not care how anyone behaved. She lost fourteen to nine. The name now crossed Brine control in Sena's voice.

"Patient Distance clear of dock. Beginning fusion departure."

Brine answered with local traffic, radiator hazards, and no blessing.

The fusion drive lit. Acceleration pressed Kessa into the work seat. Habitat docks narrowed behind them. Accord of Dust curved along the settlement plane, too large to move casually and no longer pretending that immobility meant failure.

For nine hours, Patient Distance crossed ordinary space toward Coda-Seven. The crew checked vane loads, ate one meal, rejected an automatic clock correction, and asked consent again at the last safe turn.

Eight remained aboard.

The wake fiber appeared ahead as a single displaced star. Then a second star bent around the same invisible line. Unlike an anchor corridor, it offered no mouth and held no stable width. Its decay map changed while they approached.

Sena took manual control. "Entry in sixty."

Kessa set Tomis's torque key into the calibration slot and wrapped her scarred hand around the handle.

"Port edge still thinning," Anu said.

"Vane Six low gain," the engine worker confirmed.

"Withdrawal authority remains individual," Sena said. "Call it if your local load crosses limit."

The numbers counted down.

At ten seconds, a faint gradient touched the key. No three-beat pulse followed. The fiber carried only the stretched tremor of the old molt, fading as it traveled.

Patient Distance entered at fusion speed.

Stars slid rather than doubled. The port vane loaded, eased, then loaded again. Sena corrected two degrees starboard. Brine's transmission stretched behind them, voices lowering as local time separated along the wake.

The first gradient peak arrived early. Vane Two climbed toward its limit while Vane Six reported almost no load. A fixed corridor would have hidden the imbalance behind cage correction. Here, it pushed the ship into a slow roll.

"My local crosses amber in eight seconds," the drive worker said.

"Withdrawal remains open," Sena replied.

"Hold entry. I can unload with drive trim."

Kessa felt the torque key. The drag came from port, smooth and declining. "Two

percent trim, no more.”

Fusion thrust shifted through the hull. Vane Two eased below amber. Six picked up the outer edge. The ship's roll stopped at one point seven degrees and reversed without any field pressing against the fiber.

Anu marked the event for review. Nobody renamed it routine. Their first useful correction entered the archive with the withdrawal call that almost accompanied it.

Kessa read the first shear measurement aloud. Anu published it before the next arrived. The log marked an acknowledgment window six weeks ahead, when Nacre could receive the values and answer.

No captive body held their course.

The ship moved into the fading thread, carrying eight people, open instruments, six weeks of distance, and enough fuel to leave if the wake asked more than they would take.
